We welcome this Congress as guardians of the sanitation of the Nation In your profession we recognize the noblest school of human usefulness, and in the progress of the department of the development of the law of cure, the mitigation of suffering, the prolongation of human existence, and the efforts to discover the true principles by which life can be made "worth living" We have learned to appreciate our debt to those whose highest reward is the "still small voice of gratitude and consciousness of benefaction to the human race Gentlemen, I confidently promise your convention a worthy audience, not alone the members of your profession here assembled, nor the limited number whom this building can contain, but that vaster audience, to whom upon the wings of electrical force, your message will be daily borne far and wide to the listening ears of more than sixty millions of American citizens Sure am I that your message will be worthy, and equally that your thoughtful deliverances will be welcomed by a Continent The closer relations of mankind, which modern invention have induced, have necessarily been accompanied by an increased dissemination of disease, and the need is obvious of frequent international conferences, that, in the grand sweep of scientific observation, new discoveries in the healing art may be promptly attested and applied in counteraction Forgive me if as one of the great army of patients I humbly petition the profession that in your deliberations Nature may be allowed a hearing when remedies are proposed, that her vis medicatrix may not be omitted in computing the forces of cure, and that science may be restricted as often as possible to sounding the alarm for nature to hasten, as she surely will if permitted, to the defense of the point assailed My duty is very simple, and I fear I have already overstepped its limit, for there was indeed little more for me to say than to repeat the words of an ancient whose cottage was close by the battle field of Waterloo, and, being somewhat deaf, and hearing the sound of the artillery when the famous "pounding" was hardest, thought she heard someone knocking at her door and simply said "Come in" This may seem an unscientific illustration of auscultation and percussion, but you need not make half the noise of Wellington or Bonaparte, and I can assure you the American people will hear you and heartily say to you, as I do for them, "Come in"

The welcome was acknowledged and responded to briefly by Dr William Harris Lloyd, Inspector General of the Royal Navy, in behalf of Great Britain, Dr Léon Le Fort, of Paris, on behalf of France, Prof P G Unna, of Hamburg, on the part of Germany, Senator M Semmola, of Naples, for Italy, and Sir Charles Reyher, of St Petersburg, representing the Government of Russia Dr

Unna spoke in German, and Drs Semmola and Le Fort in French

The President of the Congress then delivered his Inaugural Address, which is published in another department of this issue of THE JOURNAL The number of members registered on Wednesday night was about 2,800 The largest number registered at a previous Congress was 3,182, in London, in 1881 But at the London Congress 1,145 resident physicians were registered, while in Washington there are scarcely 400 But not alone in numbers is this Ninth International Congress a success A glance at the programme of the Sections will show that as regards scientific value and interest it is second to no one of the preceeding Congresses

SARCOMA OF THE FEMALE BREAST

In an exceedingly valuable paper in the July number of the *American Journal of the Medical Sciences* DR SAMUEL W GROSS, of Philadelphia, presents a study of 156 cases of sarcoma of the female breast, which will be all the more interesting to those familiar with the chapter on sarcoma in his work on "Tumors of the Mammary Gland," in which is made the best existing attempt to determine the relations between the minute features and the clinical characters of sarcoma of the breast As already said, the cases studied in this paper number 156, including 19 of the author's cases

Of the varieties of sarcoma, says the author, the spindle-celled, which include the fibrous, constitute 68 per cent, the round-celled 27 per cent, and the giant-celled 5 per cent of all cases Of the subdivisions 50 per cent are cystic, including the barren and proliferous cysts, 50 per cent are solid or monocystic, 33 per cent are adenoid, the glandular structures persisting principally in the spindle-celled growths, 12 80 per cent are myxomatous, the combination being almost peculiar to the spindle celled and cystic tumors, 7 69 per cent are telangiectatic and hæmorrhagic, 7 per cent are cystoid, or the seat of softening cysts, 2 56 per cent are osteoid, 2 56 per cent are calcifying, 1 21 per cent are cartilaginous, 1 92 per cent are alveolar, 1 21 per cent are lymphoid, and 1 21 per cent are melanotic or pigmented

Circumscribed sarcomata, like other encapsuled neoplasms of the mamma, are ovoid, rounded or spherical, lobulated or bossed, seldom smooth and uniform, the surface irregularities are most marked in the cystic variety They are not, as a rule, attached to the gland, but push it aside, compress and flatten it, or cause atrophy of the gland The pure spindle celled and giant-celled tumors are firm, like fibromata, while the round celled are soft and elastic, but in about one-third of all cases the spindle-celled are soft, in which cases they are composed of small fusiform cells, or have undergone myxomatous or fatty transformation, or are the seat of interstitial hæmorrhage In about one-sixth of all cases the round-celled are hard, when they are usually rich in fibrous intercellular substance, they are therefore not synonymous with soft, medullary, or encephaloid sarcomata, though they are generally softer than the spindle-celled sarcomata on account of their structure As important points in the diagnosis between the small adenoid spindle-celled growths (adenoid sarcomata of Billroth) and fibromata of the same size, it may be mentioned that of the five specimens of the former which Dr Gross has extirpated all were lobulated, firm, elastic, adherent to the gland, grayish-white in color, and tough on section, while the fibromata are hard, merely nodular, less adherent to the mamma, white, and more compact and tough on section

It is infrequent that mammary sarcomata inflame and suppurate, but ulceration of the superjacent tissues occurred in 18 59 per cent of the cases collected—more than double as large a proportion as in fibroma As with fibromata, the ulceration seems to be the result of inflammation and gangrene, or merely rupture of the attenuated skin, rather than of infiltration by sarcomatous cells, but in one case it was due to exploratory puncture In 10 per cent of the cases the ulcer is in the form of a sloughing patch While fungous protrusion almost always follows perforation of the skin, in one case the ulcer healed The fungous protrusion, usually an intra cystic growth, varies from one-half up to 5 inches in diameter, exhales a sanguinolent and fetid discharge, which may become more or less purulent, the protrusion is not very prone to free hæmorrhage or sloughing The ulcer is usually circular, and the surrounding skin is generally not only free from coloration, but it is not attached to the fungus, and is everted, or rather elevated, on its sides Sometimes there are several ulcers, separated by bridges of sound tissue Ulceration occurred in 7 69 per cent of solid sarcomata, and in 18 76 per cent of cystic sarcomata, and was met with in 25 per cent of the giant-celled, 23 58 per cent of the round-celled, and in 17 58 per cent of the spindle-celled sarcomata

Of the 156 cases only 10 tumors were multiple, sarcomata of the breast are therefore generally solitary They are most commonly situated in the vi-

cinity of the nipple, and are usually found at the upper and outer quadrant of the breast when they arise from the circumference of the organ If central they are generally cystic, while when they arise from outlying lobes they are usually solid In either case they are disposed to extend beyond their capsules, those of central origin invading the whole gland and the surrounding soft parts, while peripheral sarcomata infect the latter structures and finally invade the whole breast Sometimes they are pedunculated, but usually they form broad based hemispherical tumors Of the cases in which the age was given, 148, 1 occurred as early as 9 years, 14 between 10 and 19 years, 16 between 20 and 29, 40 between 30 and 39, 39 between 40 and 49, 23 between 50 and 59, 14 between 60 and 69, and 1 at 75 years Only 4, 2 70 per cent appeared before the age of 16, or during the formative stage of the mamma, 67, 45 27 per cent between 16 and 40, the period in which the breast and genitalia are in most active function, and 77, 52 02 per cent, during the period of functional decline—after 40 years The average age for the development of the spindle celled tumors was 36 years 7 months, for the giant-celled 47 years 3 months, and 48 years for the round celled The average age for cystic sarcomata was 38 years 5 months, and for the solid sarcomata 43 years " Hence it may be said that spindle celled and cystic sarcomata are metaplasias of the functionally perfect mamma, and round celled, giant celled, and solid sarcomata are metaplasias of the declining gland " The etiology of sarcoma is certainly most obscure, its development can rarely be traced to injury or disease, it is uninfluenced by hereditary predisposition and the social state and menstrual irregularities or arrest play no important part in the production of the neoplasm

As regards the increase of sarcoma, it is more rapid than that of any otner neoplasm, but is very varied, being independent of the age of the patient, and influenced by the structure of the tumors, by their degeneration, and by the absence or presence of cysts Like cystic fibroma, sarcoma may remain stationary and of small size for a long time, when, without apparent cause, it suddenly begins to grow, and so rapidly that a nodule that has been 15 years in attaining the size of a walnut reaches that of a double fist in 3 months, or one that has been quiescent and of the size of a walnut for 25 years, suddenly begins to grow, and measures 18x14 inches in 3 years In these cases rapid accumulation of fluid and solid contents in the dilated ducts may be looked for, or the increased size may be due to myxomatous changes and interstitial hemorrhage The influence of increased flow of blood to the mamma, which has been assigned an etiological rôle by some authors, is not borne out by the cases analyzed by Dr Gross In short, the growth of sarcomata of the breast is so capricious that no average rate of increase can be assigned to them " On the whole, however, one is justified in concluding that the small celled, the cystic, the myxomatous, and the telangiectatic increase more rapidly than the large celled, the solid, and the pure tumors " Elevation of the temperature of the breast may be said to be characteristic of telangiectatic and rapidly proliferating growths Careful investigations in regard to temperature may establish some useful points in the diagnosis of connective tissue tumors

---

In 1880 Dr S W Gross established the fact that all the varieties of sarcoma are malignant, and a study of 92 of the 156 cases now under consideration confirms that view Of the 92 cases 1 ran a natural course, being a case of round celled sarcoma of both breasts that proved fatal, with presumed secondary deposits, in 7 months from its first appearance The remaining 91 were operated on Of these 32 were well from periods varying from 1 month to 10 years and 3 months, in 42 there was local recurrence, in 8 there was both regional recurrence and mestastasis, 3 recurred, with evidences of general dissemination, in 4 cases there were metastases, and in 2 cases presumed metastases without recurrence So that 64 83 per cent of these cases were malignant 32 patients were well for an average period of 49 months and 10 days after the operation, the disease having existed for an average of 69 months and 11 days before operation, making the mean life of these patients almost 10 years Of the reproductions 57 7 per cent took place in 6 months, " while after 12 months there were only 13, or 28 8 per cent, and of these there were only 4, or 8 8 per cent after 2 years These statements lead to the belief that the chances for the patient are relatively good after the lapse of 2 years, and that the prognosis is all the more favorable as the period of freedom from signs of local contamination prolongs itself " The average date of recurrence was 10½ months, but the histological character of the growth appears to exert a marked influence on the date of recurrence The average date of the round-celled was 4 months and 20 days, for the spindle-celled 11 months 27 days, for the giant-celled 12 months 10 days Cystic tumors recurred in 8 months 5 days, and simple in 13 months 9 days—a contrast

which is "more striking when we state that the average date of recurrence for cystic round celled growths was 3 months and 4 days as against 6 months and 8 days for the simple round celled, and 9 months for cystic spindle-celled as against 16 months for the simple spindle-celled "

The age of the patient and the size and rate of increase of the tumor materially influence the prognosis Before the age of 35, when the mamma is most active, a small slowly growing sarcoma does not return, while a rapidly growing tumor, especially if cystic, will very likely recur The cases do not bear out the statement of some authors that the more tender the age the more rapid the growth of, and the more malignant, the sarcoma The analysis shows that "a sarcoma occurring in a functionally active breast evinces a marked disposition to recur after operation, with less disposition to metastases, while a sarcoma of the declining breast recurs less frequently, but is generalized in a greater number of cases " The histological character and stage of evolution of the tumor also affect the prognosis While the round-celled are most malignant, metastasis of the spindle-celled variety may be asserted, nor can it be said that cystic sarcomata are innocent or of limited malignancy, as it recurs in more than one-half the cases, and becomes generalized in 1 of every 9 cases The general and inaccurate statements regarding the malignancy of sarcomata lead to the belief that cystic sarcomata have been confounded with other cystic growths which do not infect the system Like carcinoma, sarcoma is a malignant growth, but differs from it in less frequent invasion of the skin, chest walls and paramammary tissue, less frequent invasion of the axillary glands, less frequent local recurrence after removal, more frequent metastases found *post mortem*, having a greater average duration of life (81 to 39 months), and more permanent cures (13 18 to 10 39 per cent, 4 years being taken as the period of safety)

Small, slowly increasing fibrous sarcomata are difficult of diagnosis, as they may be confounded with fibromata, especially when they arise at the circumference of the mamma "The diagnosis is based on their indolent origin, mobility, elastic or unequal consistence, their tendency to ulcerate, the not infrequent discoloration of the skin, and enlargement of the subcutaneous veins, and, possibly, elevation of the temperature, upon the suffering which they awaken late in the disease, and upon their greatest frequency after the fortieth year " Before the age of 16 fibromata and sarcomata are the only tumors met with, the former being twice as frequent as the latter Fibromata are always solid and grow slowly, sarcomata are cystic in 75 per cent of all cases, and medullary in the remaining 25 per cent, and usually grow rapidly Hence, at this period of life cystic and medullary tumors are sarcomata The more complete diagnosis of the varieties of sarcoma, as given by Dr Gross, is of sufficient interest to give entire in another column (p 336)

As regards the treatment of sarcoma little need be said "The entire breast, along with any skin that may be invaded, must be extirpated, especial care being paid to the complete removal of every particle of paramammary fat and the fascia of the pectoral muscle, in which tissue experience shows that recurrence takes place In the event of repullulation, the growths should be freely excised as fast as they appear, as such practice not only prolongs life, but may bring about a final cure " While the recurrent regional disease is more intense than the primary, and other recurrences follow rapidly, removal of the growths as fast as they appear alleviates suffering, prolongs life, averts visceral infection, and may lead to cure

SERIOUS ACCIDENT TO DR WETMORE —On Friday night, Sept 2, Dr A Wetmore, of Waterloo, Ill , walked off the St Louis special train *en route* to Washington, and received serious injuries to the head He was found in an unconscious condition near Pennboro', W Va , by a night watchman of the Baltimore and Ohio Railway, with a deep long wound in the head Late dispatches state that he is now improving, and will probably be well enough in a few days to be removed to his home

SOCIETY PROCEEDINGS.

AMERICAN DERMATOLOGICAL ASSOCIATION

Eleventh Annual Meeting, held in the Hall of the State Medical and Chirurgical Society, Baltimore, August 31 and September 1 and 2, 1887

WEDNESDAY, AUGUST 31 FIRST DAY

The Association was called to order by the PRESIDENT, DR H G PIFFARD, of New York

DR R W TAYLOR, of New York, read a paper on

TOXIC EFFECTS OF IODOFORM

The author reported the details of 24 cases, 9 of which came under his personal observation Sixteen of these cases were accompanied by constitu-

tional disturbance, while in 9 the rash existed alone without any apparent systemic symptom A large number of cases have been reported in which toxic constitutional effects have followed the use of iodoform It is evident that the toxic effects of iodoform are more frequently manifested by systemic irritation than in cutaneous manifestations The drug may set up inflammatory disturbance of the skin without apparent constitutional reaction

The skin affections may be classed under the general head, of dermatitis, but for the sake of accuracy may be further subdivided, according to their relative frequency, into erythema, eczema, and purpuric spots The erythema due to iodoform may present many of the features of similar eruptions Its mode of invasion is prompt and extension rapid It may commence at the point where the application has been made, or other patches of erythema may begin in other parts and extend to meet that from the original point Erythema may follow from simply smelling the iodoform The eruption completes its evolution in a few days and under favorable circumstances this eruption rapidly undergoes involution, behaving much as an ordinary exanthematous eruption Various forms of erythema have been noted Sometimes it is very superficial In other cases it is still superficial but of a deep red hue, and may be termed scarlatiniform In exceptional cases, usually those presenting grave constitutional symptoms, the erythema presents points of resemblance in hue and brawny feeling to erysipelas Other cases may be placed under the head of erythema multiformis The eczema resulting from the use of iodoform is usually of severe form and rapid evolution It may begin at the point of application or in parts at a distance It may also result from simply smelling the drug Its character is pronounced from the first A large surface is involved and in all respects it is similar to ordinary eczema marginans The involution is as a rule almost as rapid as the evolution if the drug is removed In some instances, however, the eruption shows a tendency to become chronic It is usually amenable to treatment Eczema occurred in 9 of the 25 cases reported

The time of the appearance of the eruption was noted as follows In 12 cases it began within a few hours, or within the first day, in 2 on the second day, in 3 on the third day, in 1 on the ninth day, in 1 on the twelfth day, and in 2 on the fourteenth day This is in contrast with the statistics of the onset of the symptoms where systemic poisoning results In the majority of these cases the morbid symptoms begin in the second week As a rule it may be stated that in proportion as the rash is slow in appearing, so are the concomitant symptoms severe Statistics seem to show that the cutaneous manifestations are most frequent in youth and middle age, while the systemic symptoms occur most frequently in the aged The erythema appearing upon the hands of dressers in hospitals as a result of the direct contact of the iodoform was regarded as being related to the ordinary hyperæmia induced by mustard and other irritating applications, and not to be considered as belonging to the class of cases described

Dr J Nevins Hyde, of Chicago I have seen the eczematous form of eruption, and also erythema multiformi, and in one case there was a bullous type of eruption resulting from the use of iodoform This occurred in a young man who had an operation performed for necrosis of the tibia Iodoform was used in the dressing of the wound The recovery was complicated with recurrences of erythema upon the surface of the body This occurred in the form of large areas of a vivid bright color, afterwards becoming dull Scattered over these surfaces were large bullæ containing a clear transparent fluid, and when ruptured produced superficial excoriated surfaces The condition was finally traced to the iodoform application, and within ten or twelve days after the discontinuance of the iodoform the eruption disappeared and did not recur I would dismiss from this category all cases in which iodide of potassium is given internally at the time that the iodoform is applied externally I suspect that in these cases, when the eruption occurs, it is due to the iodide of potassium, for we occasionally see cases in which iodide of potassium has been taken for a certain period without unpleasant effects, suddenly present manifestations of iodism as the results of some transitory condition, as change of climate, temperature, etc

Dr J C White, of Boston I have seen a number of cases of eruptions due to the free use of iodoform in the treatment of surgical injuries I have never seen systemic manifestations resulting from its use in cases where there was dermatitis The form of eruption has varied from simple hyperæmia up to the vesicular form, and going no further in most cases In occasional instances there appeared a furuncular form of inflammation, owing, possibly, to mechanical obstruction of the cutaneous follicles by particles of the powder The eruption is almost always found in the immediate vicinity of the point of application When the remedy is applied in the form of a powder it may easily be transferred to other parts of the body, and thus cause an extension of the eruption I have never seen any affections of the mucous membrane resulting from the use of iodoform, nor have I seen any purpuric eruption follow its use

Dr R W Taylor With reference to Dr Hyde's remarks in regard to the influence of iodide of potassium in those cases in which it was administered in connection with the local application of iodoform, I would state that in one case the eruption came on when the patient was not taking iodide of potassium, and was relieved when the iodide was given In one case the patient (a physician) thought that the eruption was worse when he was taking iodide of potassium, but the eruption always promptly followed the use of iodoform when no iodide was taken

Dr I E Atkinson, of Baltimore, read a

CLINICAL STUDY OF ERYSIPELAS IN CHILDREN

The author considered erysipelas to be a contagious infectious disease It has not yet been determined whether it is due to one special microorganism, or whether it may be produced by several The study

of the affection as it occurs in children offers some opportunities for the solution of this question During the first month erysipelas is extremely fatal, but the mortality gradually diminishes up to the end of the first year The fatality at this period of life is probably to be attributed to its dependence upon the poison of puerperal fever The author reported the detailed histories of three cases of erysipelas in young children In two of these cases a cellular board-like induration occurred as the result of intense œdema and cellular infiltration In neither of these cases was there suppuration The speaker thought that erysipelas should be considered the expression of the effect of one of a number of specific causes, and in that sense should be regarded as a symptomatic inflammation

DR J C WHITE, of Boston The author mentioned erysipelas as a contagious disease Does he personally know of a case in which it was directly transferred from one person to another He also referred to the use of the tincture of chloride of iron in the treatment of the disease, does he regard this as producing any specific therapeutic action?

DR ATKINSON Personally I have not seen an example of the direct contagiousness of erysipelas, but there are a number of well authenticated cases on record I cannot say that tincture of the chloride of iron is a specific, but in my experience it has had a more favorable influence on the course of the disease than any other remedy that I have employed

DR WHITE I have never seen a case of facial erysipelas transferred from one person to another If at all contagious, it must be so with extreme rarity I regard tincture of the chloride of iron and all other internal remedies as useless in the treatment of this form of erysipelas For five years I have given no internal medicine in the treatment of erysipelas, and I have not seen a case in which the erysipelas eruption did not disappear in from five to ten days In my experience, infantile erysipelas has been so wholly unlike, in its clinical aspects and its course with or without treatment, ordinary traumatic erysipelas, that it seems to be quite a distinct disease

DR J NEVINS HYDE I have seen one case which seemed to indicate the contagious nature of erysipelas A young mother soon after confinement had her ears pierced for ear-rings This was shortly followed by typical erysipelas spreading over the face and scalp Soon the nursing child was affected with the disease and presented typical erysipelas, from which it promptly died I agree with Dr White that the tincture of chloride of iron is useles in the treatment of the affection, although I consider it harmless

DR ATKINSON In those cases of erysipelas which may be termed septic, whether the disease depend upon ordinary septic poison or not, I have no doubt that benefit is derived from the administration of the tincture of iron in large doses, as much as 3ss three or four times a day

DR R B MORISON, of Baltimore, read a paper on

LEUCOPATHIA UNGUIUM, A PECULIAR AFFECTION OF THE NAILS

The ordinary white spots found on the nails are well known, they are gradually forced to the outer edge of the nail by the growth of the new nail behind, in from 4 to 6 months These spots are usually irregular in shape A young lady, age 20, recently came under the author's care, in whom these spots were uniform The nails showed white bands $\frac{1}{16}$ inch wide, extending across the nail from border to border The nails were perfectly smooth, and in other respects normal, and the general health good These white bands had appeared regularly for many months During the previous summer the bands disappeared almost entirely The toe nails were not affected, and the hair was not grey Microscopic sections were made by cutting the white lines at right angles By direct light the lines appeared of a a pure white, while the remainder of the section was of a dark color Acetic acid and other agents caused the lines to disappear, as did Canada balsam It seemed clear, then, that the lines were due to air-spaces in the nails

DR J NEVINS HYDE, of Chicago, read a paper on

THREE CASES OF SIMULTANEOUS HAND AND FOOT DISEASE

Case 1—C B, æt 19, came under observation in May, 1887 Family history good, he denied specific disease Three years ago he noticed the first signs of the present affection on the fingers and later on the toes The disease then extended to the palms of the hands and the soles of the feet The local affection had gradually increased, and he complained of the stiffness thereby induced The free border of the nails was tilted away from the fingers, and the space thus left was filled with hardened matter The substance of the nail was dry and rugous He had recently noticed some sweating of the hands The palms of the hands and soles of the feet presented a condition of tylosis The nails of the toes were tilted away from the phalanges, and presented a condition similar to that seen in the nails of the fingers There was also bromidrosis

Case 2—A female, æt 24, family history good The patient presented tylosis of the hands and feet, which continually recurred Careful examination showed her general condition to be fair The pulse was unusually slow, 50 a minute in the sitting posture The hands were cold and bathed with profuse perspiration The finger-nails were somewhat rugous, and tilted from the fingers, and the space filled with grayish masses The same condition existed in the nails The palms of the hands and the soles of the feet were simultaneously involved, showing callosities Every six or eight weeks there was a reformation of the masses on the soles of the feet At no time did the tissue beneath these masses present a sound appearance Treatment with various measures, continued for a long period, had no apparent effect

Case 3—Male, æt 28, with a good family history and no history of syphilis, for two years had noticed some numbness of the lower extremities, especially marked at night There was entire absence of hair on certain parts of the lower extremities He stated that 15 years before, he had been struck on the head

with a brick, and that a few years before coming under observation an operation had been performed upon the head, the exact nature of which he could not state The hands and feet were habitually cold Broad vertical areas, chiefly on the outer aspects of the limbs, were found in which not a single filament of hair could be detected Two of the finger nails of the right hand showed marked vacuolations

DR L A DUHRING, of Philadelphia I do not recall a case of white spots upon the nails in which the distribution was as uniform as in the one described by Dr Morison I have however, met with cases calling for treatment I have regarded the affection as dependent upon a want of nutrition in the nail tissues, and with that view have used arsenic with satisfactory results This acts upon the nervous system, improving the nutrition of the whole member and the finger nails in particular

DR P G UNNA, of Hamburg With reference to Dr Morison's paper, I would say that we know from the labors of various investigators that the presence of air in the horny tissues is always a secondary phenomenon The horny masses must be changed before they will allow the entrance of air These white spots in the nails are analogous to medullary substance I have seen cases similar to those described by Dr Hyde, in which the affection was not only simply of the nails, but also of the hands and feet, and I have allied them with eczema My principal reason for so doing has been that in some cases I have seen combined with the disease of the hands, patches of eczema on various portions of the body

DR R. W TAYLOR, of New York I should regard the cases described by Dr Hyde as ordinary cases of tylosis of the hands and feet This may occur idiopathically, or as a result of chronic eczema, or as a result of chronic syphilitic psoriasis

DR LEGRAND N DENSLOW, of St Paul I am not in accord with Dr Hyde in his view of the nature of the cases he had described I have regarded such cases as instances of callosities With reference to treatment, I would say that in my last case, in the person of a hotel porter who was unable to perform his duties on account of the tender condition of the soles of his feet, I first removed the callosities by the application of a saturated solution of salicylic acid in collodion, and then made a false sole for the feet by the application of belladonna plaster spread upon kid By this means he is able to attend to his work in comfort

DR L D BULKLEY, of New York I have under my care a patient who presents a condition of the nails very similar to that described by Dr Morison She is a sufferer from gout, and from her family history I thought these lines were possibly gouty deposits I think, however, that Dr Morison has shown their true nature

I agree with Dr Taylor in considering the cases reported by Dr Hyde as closely allied in their nature to cases of eczema In the treatment of these cases I have derived considerable benefit from keeping the parts constantly macerated by the use of an oiled-silk lining sewed into an ordinary stocking and worn constantly, night and day

DR E WIGGLESWORTH, of Boston I have now under treatment a case similar to those described by Dr Hyde I have regarded it as a case of tylosis In the treatment I have employed a 20 per cent solution of salicylic acid in emplastrum saponis until the callosities were removed I have then dressed the parts with equal parts of belladonna and mercurial plaster spread on kid Regarding the condition as dependent upon lowered nutrition, I also employed tonics with good effect

DR G H TILDEN, of Boston In connection with Dr Morison's paper I would mention a case which I recently saw It was a case of two nails growing on one finger, one above the other The patient had one year ago met with an accident which destroyed the nail, and evidently split the matrix into two halves, and each half had produced a separate nail

THE PRESIDENT The affection described by Dr Morison is one with which, in its mildest form, we are all more or less familiar The most aggravated case that I have seen has come under my observation within the last two weeks This case presents fully as extensive leucopathia as the case reported to-day, although not so regularly distributed This condition is analogous to leucopathia of the hair, in which I have satisfied myself that the condition is due to fatty degeneration of the cells and subsequent absorption of the fat In the case of the nail, after the absorption of the cells which had undergone fatty degeneration, the horny nature of the tissue would prevent closure of the cavity, which would remain filled with air

DR HYDE I would merely state that, like Dr Taylor and Dr Bulkley, I first regarded these cases as instances of tylosis, but a large experience showed that this view was not correct In one case I have watched the course of the disease for three years The parts have been macerated for days and weeks at a time I know that there is a constant new formation of these masses I know that the nails are continually undergoing a similar process These cases are entirely different from the ordinary forms of tylosis and callosities

AFTERNOON SESSION

DR L DUNCAN BULKLEY read some

CLINICAL NOTES ON PRURITUS

Pruritus or itching is an extremely common symptom resulting from various causes, many of which are recognizable There are a certain number of cases in which the pruritus appears without apparent cause It was only this last group of cases that were considered In the present state of knowledge, it is not possible to determine the exact lesion in these cases Pruritus may be defined as a functional disturbance of the nerve elements of the skin, resulting in itching, and dependent upon local irritation or local lesion Out of a total of 5,000 cases of general skin diseases the author had records of 80 cases of pruritus, a proportion of about 1 75 per cent 30 of the patients were females and 50 males In the majority of cases there was some chronic disease, such as

gout, albuminuria and chronic bronchitis, or marked evidence of lowered general vitality The cases were classed under the following heads, according to frequency Pruritus hiemalis, pruritus genitalis, pruritus ani, pruritus vulvæ, pruritus scroti, and pruritus senilis In quite a number of instances, the pruritus proved rebellious to treatment Temporary benefit was obtained in some cases, while in others no relief resulted from treatment The author was of the opinion that in many cases the condition resulted from reflex irritation In connection with this subject the author referred to 115 personal observations which he had made These consisted in the production, either accidentally or intentionally, of a point of irritation in some part of the body, and in noting the point at which itching was experienced The observations were made with the object of determining whether or not there were crossed reflexes The reflex sensations cannot be induced at will, but seem to be more readily brought about when the body is fatigued 84 of the observations related to the right side of the body, while 31 relate to the left In all but 3 cases the reflex occurred on the same side as the point of irritation These three exceptions were as follows irritation on inside of right knee, reflex itching felt at left scapula, irritation of right thigh, four inches above the knee, reflex at the insertion of the left deltoid, irritation of the left heel, reflex at right side of the pubes Irritation in the same locality will frequently, on different occasions, produce reflexes in entirely different localities The results have been so varied that it is impossible to classify them into definite groups

DR F B GREENOUGH, of Boston, read some

CLINICAL NOTES ON PEDICULOSIS

The speaker had been induced to examine this subject on account of the fact that the statistics of the Association had shown that there was a greater proportion of cases of pediculosis reported from Boston than from any other city He had found, taking the statistics for nine years, that the proportion of cases of pediculosis to the total number of cases of disease of the skin was, in Boston, 5 5 per cent , in New York 3 per cent , in Philadelphia 3 33 per cent , Baltimore 2 12 per cent , St Louis 1 5 per cent , Chicago 3 per cent , and Canada 3 3 per cent In 1884 New York reported, out of a total of 2,737 cases of skin disease, no cases of pediculosis of the head During the same year the number of cases of pediculosis pubes reported from Chicago equaled that reported from all of the other cities The only explanation of this fact that can be offered is that the difference is more in observers than in the number of cases of the affection An observer in one city may put under the head of eczema capitis a case which would be considered in Boston as one of pediculosis capitis There are three different forms of pediculi the pediculus capitis, the pediculus corporis and the pediculus pubis, and these pediculi are rarely seen except in their own locality The presence of pediculi in large numbers causes cutaneous trouble So far as the efflorescence goes, the eczema thus induced is identical with that due to other causes The distribution and other conditions make the diagnosis easy The speaker had only in one instance noted the pediculus corporis on the skin, and he thought it possible that they may feed without leaving the clothing

DR L H DUHRING, of Philadelphia My experience with a certain number of cases of pediculi vestimentorum is that they do leave the skin, and I have seen them feeding upon the skin

DR J C WHITE, of Boston In regard to diagnosis, I have seen cases in which I have been able to make the diagnosis without looking at the head In children, where there is an eczematous eruption in certain respects resembling impetigo contagiosum, located around the orifice of the mouth, the nostrils, and the lobes of the ears, I make the diagnosis of pediculosis of the scalp Another practical point is that pubic lice do not always confine themselves to one locality, but may be found in different parts of the body Careful examination will show them not only in the axilla, but also in the lower extremity In one case, that of a child, I found the pubic lice in the hair of the head If the treatment is limited to the pubic region the results may be unsatisfactory In the treatment of pediculosis of the pubic region and of the head I always use crude petroleum This does not produce the slightest irritation upon the most inflamed surface It is allowed to remain in contact with the hair for two or three hours

DR P G UNNA, of Hamburg In Vienna it is the custom to consider every case of pustular eczema of the head and scalp as due to pediculi, without making any further examination This is, I think, a mistake Although pediculi may be present in these cases they may only be secondary manifestations, resulting from the good feeding ground furnished by the diseased surface

DR J N HYDE, of Chicago The great predominance of cases of pediculosis pubis in Chicago, which has been referred to by Dr Greenough, may perhaps be explained by the fact that during the winter season, when navigation is closed, many seamen congregate there During the summer these men have been engaged along the coast, and have indulged in all kinds of debauchery They come under observation often in a very vile condition, suffering with syphilis, pediculi and blenorrhagia

DR L D BULKLEY I have heard no reference to a little lesion made by the perdiculus corporis, to which attention has been directed by Dr Tilbury Fox, and one which he considers of diagnostic value This is a little hæmorrhagic spot resulting from the insertion of the proboscis of the pediculus into the follicle of the skin in the process of feeding I should like to know if any of the members here have put any trust in this as a diagnostic sign?

THE PRESIDENT A number of years ago I collected several pediculi vertimentorum and watched the process of feeding I was able to verify the statement of Dr Tilbury Fox The sucker of the pediculus corporis is not a cutting instrument It is apparently inserted into a follicle After its removal a minute droplet of blood will appear, which after a few hours becomes black This sign is often of consid-

erable value in diagnosis In the treatment of this affection crude petroleum seems preferable to kerosene, which is sometimes used I know of two cases in which the use of kerosene produced a violent dermatitis Crude petroleum is less irritating

Dr J C White, of Boston, read an

INTRODUCTION TO THE STUDY OF DIET IN THE PRODUCTION AND TREATMENT OF SKIN DISEASES

Many articles of diet are considered both by the people and by the profession as injurious in certain affections of the skin The author held that in regard to many of these articles, there was no evidence of their injurious effects, with the exception of popular belief, and that they should not be discarded until more proof was advanced against them Among various substances considered injurious in skin diseases, butter was mentioned, but the author regarded pure uncooked butter as entirely harmless so far as the skin is concerned Oatmeal and buckwheat have been classed in the same category, but the speaker thought that there was no foundation for such a belief The same remarks would apply to fish and meat, which have been regarded as harmful by some dermatologists Dr White then mentioned certain articles which in his experience had seemed to be prejudicial in certain skin affections Alcohol aggravates the course of inflammatory condition of the skin In some, lager beer will produce a crop of acne over the lower half of the face The eating of acid fruits may cause an acute eczema Strawberries often cause urticaria Apples are said to produce an acneform efflorescence about the mouth Some nuts, especially the English walnut, may produce inflammation of the mucous lining of the mouth Shellfish and crustaceans may occasionally give rise to urticaria Other meats may at times produce similar effects The worst case of giant urticaria that the speaker had seen had followed the use of roast turkey

Dr J N Hyde I can agree with the speaker in regard to most of the articles mentioned I should, however, put oatmeal on the black list I have seen a case in which facial efflorescence is always produced by the ingestion of this article, even when used without the addition of anything else I have in several cases thought that urticaria had been induced by the use of the Natal or seedless orange When urticaria follows the use of the grape, I think it is principally due to the fact that the seeds and skin of the grape are also swallowed

Dr E B Bronson, of New York While these articles of diet may have no specific effect on the production and course of skin affections, they may act in a reflex manner by causing disorders of the digestion Many of them probably owe their effect to the fact that they are unaccustomed articles Newly arrived emigrants frequently suffer from erythema and urticaria, this is especially true for emigrants from Ireland This I have attributed to the radical change made in the diet and have had good results by ordering the patient to return to his former diet consisting largely of potatoes

Dr E Wigglesworth, of Boston I think that with oatmeal the effect depends largely on the size of the grain and the method of cooking If not thoroughly softened it may cause irritation of the mucous lining of the stomach and bowels, and induce urticaria, which as a result of scratching may pass to secondary eczema It seems to me that salt air has some injurious effects in cases of eczema My patients with eczema are better in the mountains than at the sea shore In the case of acne it is the reverse, such patients are usually benefitted by the sea air

Dr G H Rohe, of Baltimore There seems to be no doubt that certain articles, such as crabs and oysters, affect the skin more frequently than other articles, and yet I know of no article so readily digested as oysters The fact that they are unaccustomed articles of food may explain their effects to a certain extent I have seen pruritus induced, as I supposed by the use of buckwheat

Dr P G Unna In my private hospital I allow a liberal diet, and I rarely find it necessary to impose any restriction I make it a point, by close questioning, to find out what articles seem to unfavorably influence the condition, and then direct that they be avoided I have seen urticaria produced by strawberries in cases in which the berry has not been swallowed, but simply placed in the mouth

Dr L D Bulkley I have more than one patient who cannot take raspberries without having urticaria In some cases pineapples have a similar effect Personally I pay a good deal of attention to the diet Milk has not been referred to, I see many patients in whom injurious effects have followed the use of milk with the meals If taken between meals it produces no injury I have found that almost every case of acne is aggravated by soup taken with the food

Dr LeGrand N Denslow, of St Paul I think that in this connection the quantity of food taken is of importance Many people who do not lead active lives eat too much, and I have found it of advantage in certain cases to restrict the patient to one meal a day, allowing him, however, to eat all that he wants at this time I would add to the injurious articles already mentioned, pork, veal, and anything fried

(To be concluded)

BASLE AND FREIBERG[1]

Formation of Fat and Causes of Obesity—Immediate Coaptation in Compound Fractures—Skin Grafts—Scoliosis in School children—Hydronephrosis—Antagonism of Germs—University of Basle—Antiseptics—Socin—Fæcal Fistula—Excision of Larynx for Carcinoma — Supra pubic Cystotomy — Volvulus — Intra-glandular Enucleation of Struma—Garre—Fehling — Hegar — Myo fibroma Uteri—Colpo perineorrhaphy—Wiedow—Kraske—Extirpation of High Rectal Cancer—Coxitis—Osteotomy for Rickety Legs

Dear Dr Fenger —While in Basle I attended the meetings of the Medical Society of Basle and of the

[1] By permission of Drs Fenger and Senn

Central Verein, the latter is a National society representing the German Cantons, and has 1,100 members The Basle Medical Society met the evening before the meeting of the Central Verein, and was attended by many of the visitors Professor Massini, the President, made a short address and introduced Professor Bunge, who read a paper on "The Formation of Fat in the Body, and the Causes of Obesity," the subject being treated from a strictly scientific and chemical standpoint He showed clearly that fat is produced from fat, other hydrocarbonaceous food and albuminous substances The causes of fat accumulation were attributed to want of muscular exercise and consumption of alcohol He said that dieting in the treatment of obesity was useless and often dangerous, and advised as the safest, most rational and most efficient treatment, active muscular exercise and abstinence from alcoholic drinks As no one responded to the invitation to open the discussion on the paper it must be taken for granted that the views advanced represented those of the members present

The Central Verein held a meeting which lasted only one day At 9 A M the members visited the different clinics, where the directors presented interesting cases with brief practical remarks Professor Socin talked to about fifty members on the "Treatment of Compound fractures by Immediate Coaptation" He recommended the introduction of ivory pegs about three inches long, and as large as the medullary cavity, into the shafts of long bones as a direct means of coaptation He showed three cases in which this treatment had been successful, the ivory having healed in It is certainly a triumph of antiseptic surgery that such a large foreign body can be introduced into the medullary cavity without causing serious disturbances or materially interfering with the normal reparative process, but I doubt very much if Professor Socin, should he have the misfortune to sustain a compound fracture of the leg, would submit to such treatment That medullary tissue takes an important part in callus formation after fractures no one can deny, and that it is not good surgery to crush this tissue with such an enormous ivory plug hardly requires an argument I suggested to him that if such treatment is to be adopted it would be decidedly better not to use solid cylinders of ivory, but hollow tubes which answer the same mechanical purposes and would not interfere with the formation of an internal callus, and at the same time would not tax the resources of nature in her efforts to remove the foreign body by absorption For myself I should prefer to secure the advantages of immediate coaptation not by plugging the medullary canal, but by making perforations in the compact layer at corresponding points, and introducing small bone nails The perforations would only hasten the inflammatory osteoporosis, which must precede callus-formation

Several cases of genu valgum and curvature of the legs were shown in which the deformities had been corrected by osteo clasis with Robin's apparatus Socin speakes favorably of Robin's osteo clast as a substitute for osteotomy

Cases were also shown in which large cutaneous defects after operations were treated by transplantation of large skin grafts by Thiersch's method For success the whole surface must be covered with grafts, which must be very thin Usually on the third day, when the dressing is removed, the surface is found dry and the grafts firmly adherent

At noon the meeting was formally opened by the President, Dr Sonderegger Professor Kocher read a paper on 'The Prevention of Scoliosis in School-children" He believes that structural and architectural changes are produced in the vertebræ by pressure and rotation caused by faulty desks in the school room As the best and surest means to prevent lateral curvature of the spine he recommends a desk with a movable top, which can be so arranged that while the child is writing the erect position cannot be changed

Dr Haffter reported a case of hydro nephrosis cured by making an abdominal fistula

Dr Garrè read a valuable paper on "Antagonism among Germs" He has made many careful experiments to determine the effect of a culture of germs on different culture substances, and after removing the germs he inoculated the same soil with other germs From the results thus far obtained he finds that some germs affect the soil favorably for the growth of other forms of germs, while in other cases he finds a direct antagonism For example, a soil impregnated with the ptomaines of the *bacillus fluorescens putridus* remains perfectly sterile when inoculated with pus microbes These investigations have an important practical bearing

The University of Basle does not admit female students The medical class numbers 120, of this number about thirty pass their final examination annually About twenty five attend the surgical clinic The surgical wards are on the first floor of the Burgerspital, and contain eighty beds Corrosive sublimate (1 1000 to 1 5000) is used as an antiseptic, and for dressing sublimated gauze, dry, and cushions of sublimated wood-wool Catgut ligatures are prepared by simple immersion in an alcoholic solution of sublimate (1 1000), and material prepared in this way has always been found sterile by Garrè Dressings are usually not changed oftener than every eight to twelve days

Professor Socin is a splendid lecturer, an impressive and somewhat stern teacher, and a good operator He is always thorough in making a diagnosis, and never lets a student off until every "what else could it be" has been exhausted

In his wards was a young man who received a penetrating wound of the abdomen when 3 years old A fæcal fistula remained, and he was brought into the hospital and placed under Socin's care twenty years ago Examination showed that the cæcum was injured, and the fistulous opening was repeatedly cauterized, but failed to close A number of operations were performed but without avail, and the child left the hospital with the fistula About a year ago he came back for the second or third time, and as intestinal surgery had made great progress since their former attempts both surgeon

and patient had new hope of success The opening was closed at least half a dozen times, but instead of becoming smaller the fistula got larger, as at each operation more tissue was removed A few weeks ago it was determined to detach the adherent bowel more thoroughly, which was done without opening the abdominal cavity, and the parts were accurately coaptated with three rows of sutures, this time the operation was a success At present only a superficial granulating surface marks the site of the former fistula, and the patient is in excellent health

In the female ward I was shown a case of unilateral excision of the larynx for primary carcinoma of the larynx The patient was 50 years old, and had had a goitre since childhood At the time of the first operation the portion of the larynx removed was firmly adherent to the struma, and it was suspected that the disease had extended to the tumor, but it was not thought wise to expose the patient at this time to the additional risks of another serious operation The struma continued to enlarge rapidly, and as soon as the patient had sufficiently recovered from the larynx extirpation the struma was removed She recovered well also from this operation, but has been unable to take food *per os*, as during the act of swallowing it passes into the larnyx and causes asphyxia She is fed exclusively by the stomach tube She breathes through a tracheal tube, and there has been great difficulty in keeping the larynx patent, as its lumen has become greatly contracted by cicatricial tissue Dilatation is now practiced by introducing bougies from the tracheal wound upwards

The benefits to be derived from supra-pubic cystotomy are well shown in the case of a man 45 years old, who was brought into the hospital suffering from symptoms indicating stone Careful exploration failed to find a stone, but in the eye of the catheter was removed a fragment of tissue which the microscope showed to be carcinomatous The bladder was opened above the pubes, and the edges of the visceral wound stitched to the external incision Digital exploration through the opening, and examination with reflected light, showed that the neck of the bladder was surrounded by a carcinomatous mass which had evidently started from the mucous membrane The whole mass was removed with scissors, spoon and Paquelin's cautery, and the bladder drained The patient has been comparatively free from pain since the operation Though a recent examination showed that the disease is returning, the palliative effect of the operation was marked

A case of acute intestinal obstruction was brought into the hospital recently, and on palpation a well-defined tumor was felt just above the umbilicus, the abdomen was considerably distended An incision was made through the linea alba, and the tumor came at once in sight and proved to be a volvulus, a large loop of the small intestine with a long mesentery being twisted one and a half times around its axis and fixed in this position The volvulus was easily corrected, intestines returned, and the wound closed Vomiting ceased promptly, the bowels soon moved spontaneously, and the patient is now convalescent

Of the many operations which I saw I will only detail two intra glandular enucleations of struma Recent studies as to the nature and structure of struma, especially by Wolfler, have shown that in majority of cases these tumors are atheromata, and appear as distinct circumscribed tumors with a proper capsule in the substance of the thyroid gland An adenoma, when it has undergone extensive cystic degeneration, becomes a struma cystica For many years Socin has recognized these facts, and has substituted for the majority of cases what he has termed intra glandular enucleation in place of excision He claims that this operation is easier of execution, and that it does not require the unnecessary removal of glandular tissue He has done the operation fifty-seven times, and has never had a fatal result or serious complication from the operation The most important step of the operation consists in finding the exact boundary line between the glandular tissue and the capsule of the tumor If this place be not found, or be lost during the operation, the surgeon is led astray, and may incur serious hæmorrhage I was very anxious to see the operation performed by Socin, and as no case was on hand we hunted through the hospital and finally found a man about fifty years old, who had lost one of his legs by amputation for tuberculosis of the ankle-joint, and who fortunately had a struma, and enough courage to submit to another operation

The tumor was located in the median line of the neck, and was a little larger than a hen's egg A straight incision was made over the centre of the tumor, and as the capsule was adherent anteriorly some tissue was lost in separating the adhesions and finding the exact line between the capsule and parenchyma of the gland After this was found it took only a few minutes to complete the operation Hæmorrhage was arrested temporarily by compression, until the bleeding points were found and seized with forceps After bleeding was arrested the wound was drained, sutured and dressed in the usual manner

The second case came into the hospital next day, and was a legitimate case, as she had come to have the tumor removed She was forty five years old, and had had a goitre since childhood Three distinct tumors could be felt in the substance of the gland As the bulk of the mass was to the right of the median line a long incision was made along the anterior border of the sterno mastoid, and a careful dissection made down to the largest of the three tumors After its capsule was carefully exposed the enucleation was done in a few minutes Quite a number of forceps were used to arrest bleeding After all vessels were ligated the other tumors were attacked through the same incision, and removed in the same manner When all tumors which could be felt before the operation were removed, it was found that the gland was still large, and at least four more tumors were enucleated through the first incision After enucleation suturing is done very carefully first the gland tissue is stitched together, next muscles and fascia, and finally the skin Socin claims that the wounds after enucleation heal better

than after excision, and that the cosmetic effect is also decidedly better

Socin has established a nice private laboratory at his own expense in his own house, and has placed his private assistant, Dr C Garrè, in charge of it Garre has done some of the best work in bacteriology that I have seen in Germany or anywhere else Socin will find that he has made a good investment which will bring compound interest, if not in dollars and cents at least in the satisfaction that he has been instrumental in the advancement of scientific research One of the attractions in the hospital is the beautiful collection of gunshot wounds which Socin brought with him from the Franco-Prussian war, and which he has presented to the hospital museum

The chair of gynecology and obstetrics recently made vacant by the resignation of Professor Bischoff has been filled by Professor Fehling, of Stuttgart I attended the second clinic he gave, and heard an excellent discourse on congenital syphilis All the students who attend his clinic must wear linen coats, which are furnished by the hospital Professor Fehling is a thorough student and an excellent teacher, and his new field of labor will afford ample opportunity to increase the reputation he already enjoys

From Basle I went to Freiberg, i B , and remained two days for the purpose of familiarizing myself with the work of Professors Hegar and Kraske Freiberg has only 25,00 inhabitants, and yet the University has 1,100 students, of which 500 are studying medicine, an example of the over-production of medical men in Germany

Professor Hegar, by his appearance and habits, might readily pass for an American He is fifty-seven years old, but physically well preserved In his clinical instruction he is very thorough, and rarely ever takes more than one patient to fill the hour During this whole time the patient is kept chloroformed, and from six to twelve students are called upon to examine the case Hegar told me that unless the patients were anæsthetized they would not submit to such wholesale and public examinations No students who are dissecting or working in the laboratory are allowed to make these examinations, and they must disinfect their hands thoroughly with warm water and soap and spirits of turpentine When the list of names is read off and the name of a student is called who has been recently exposed to infection he answers "inficirt," when he is allowed to remain in his seat In dealing with his patients Hegar is not particularly kind and gentle, and he invariably addresses them with the familiar "du " In his examinations he is very thorough, but his manipulations are not noted for their gentleness His lecture room is always crowded with students, who appear to enjoy his peculiar temper

I was present when he performed a very difficult operation on a patient who had a complicated history and *status præsens* She was about thirty years old, and ceased menstruating in February For several weeks she had been flooding almost constantly On examination she was pronounced pregnant Professor Hegar places great confidence and importance in certain conditions of the upper portion of the cervix as an almost infallible sign of early pregnancy, and was the first to describe this condition He asserts that at the junction of the cervix with the uterus during the early months of pregnancy the tissues become so soft and yielding that on being compressed between the index finger introduced into the rectum and the tips of the fingers of the other hand applied over the pubes, it becomes almost as thin as cardboard, the tips of the fingers almost meeting, while the lower portion of the cervix, on account of the firmer anatomical conditions, has not lost its resistance Among other signs this condition was present in the case As it was almost certain the fœtus was dead, or had already passed away, he decided to clear the uterus of its contents With forceps and curette large masses of placenta were removed, and on exploring the cavity of the uterus with the index finger, to ascertain whether any fragments remained, it was found that a large interstitial myofibroma projected into the uterine cavity from the right side Under the unfavorable conditions it was deemed dangerous to leave the tumor, and he decided to remove it through the vagina On account of the narrowing of the cervical canal it was difficult to make the tumor accessible The cervix had to be dilated again and again, until finally the tumor could be seized with forceps, when it was drawn down, and the mantle of uterine tissue divided with long curved scissors, after which the tedious process of enucleation began Although only the finger and dull instruments were used the hæmorrhage was profuse, and the woman became evidently anæmic towards the end of the operation, which lasted at least an hour After the enucleation the uterine cavity was thoroughly irrigated and disinfected, and after drying it thoroughly with a sponge it was packed with iodoform gauze, with a view of securing drainage

Hegar looks upon vaginal enucleation of uterine myo fibroma as one of the most difficult operations, and in this opinion he is sustained by most operators who have had experience with the operation When a man like Hegar approaches such an operation with trepidation, how must an ordinary surgeon or gynecologist feel when he undertakes such a case? He has had sixty-seven cases of abdominal section without a fatal result His great hobby is colpo perineorrhaphy, the only operation, he says, for which he is willing to give a guarantee in every case I saw his son in-law, Wiedow, perform this operation twice, and I must say that I have never seen anything more neat and perfect before or since For suturing fine silver wire is used exclusively, and the vaginal sutures are allowed to remain for four or five weeks In a case that Hegar had operated upon two and one-half years before, and which I was requested to examine to see the final result, one of the sutures remained, and was removed this time The secret of his great success with this operation undoubtedly depends on the accurate suturing Three kinds of sutures are used alternately, so as to secure perfect approximation and coaptation deep, half

deep, and superficial The first are passed completely out of sight, the second are visible only in the centre of the floor of the wound, while the third embrace only the mucous membrane The sutures are cut quite short An ordinary long curved needle is used for passing the sutures For the dissection an ordinary scalpel is used, while the scissors only come into use in smoothing the surface

The gynecological and obstetrical wards are in a separate building from the main hospital, and contain eighty beds A good many of Hegar's and Wiedow's operations are performed in a private hospital in charge of Sisters of Mercy

Professor Kraske, formerly Volkmann's assistant, is a young, but promising surgeon who has been in his present position but a short time His wards contain 160 beds, and permit a large material for clinical teaching He is thoroughly antiseptic in his operations He has recently proposed and practiced a new operation for the extirpation of high rectal cancer, which consists in partial resection of the sacrum in order to secure better access to the disease He has performed the operation five times, and says he has reason to be satisfied with the results One of his patients who was operated on some time ago still remains in the hospital, and in a comfortable condition

During the clinic I attended he presented a number of cases of coxitis before and after operation, and made some general remarks on this disease He places great stress in placing the limb in the abducted position after the operation, so as to bring the upper end of the femur nearer to the acetabulum A moderate degree of motion in the hip after operation he considers an ideal result

He also operated on a rickety child with extreme curvature of the legs The greatest curve was near the upper epiphyses of the tibiæ, with the convexity directed outwards Osteotomy with the chisel was performed on the concave side of both tibiæ The bone was exposed by a straight incision, the periosteum divided and reflected, and with Volkmann's chisel the bone was divided sufficiently for it to be fractured by moderate manual force The wounds were sutured and dressed, and the limbs placed upon a posterior splint

As I was following Professor Kraske through his wards a messenger brought word that one of his patients had died suddenly When we reached the place one of the assistants had just finished a rapid tracheotomy, and by artificial respiration succeeded in restoring the patient The patient was an old man who was brought into the hospital a few days before with a tumor of the upper jaw and an inflammation below the tongue A sudden œdema of the glottis caused asphyxia, and life was restored only by the prompt action of the assistant

N SENN

DOMESTIC CORRESPONDENCE

ERYSIPELAS AND PUERPERAL FEVER

Dear Sir —After reading an article in THE JOURNAL of August 20, by A MacLaren, M D, I wish to give a short detail of facts in the way of counter current On August 13 I was called to see Mr T, just brought home suffering from a very severe attack of facial erysipelas, for which I attended him eight days The third and fourth days of the attendance I saw him twice daily, as he was delirious, and in a state of great prostration On the fifth day of my attendance I opened an abscess that had formed beneath the right eye, and which, on pressure, discharged a large quantity of offensive pus

At 2 A M, August 14, I was called to Mrs H, in (second) labor She was delivered at 6 A M, labor being natural and easy I dismissed her on the 18th, convalescing favorably At 6 A M August 15 I was called to Mrs G, in (first) labor She was delivered at 4 P M, having had an unusually painful and difficult labor This same evening I drew the urine with a catheter, as she was unable to pass it, and suffered greatly for an hour before I was able to attend her She sat up yesterday for the first time, and has had no unpleasant symptoms On August 20 I attended Mrs H, miscarriage at four and a half months She is doing well and has no symptoms of fever

At each visit to the case of erysipelas I washed my hands thoroughly before leaving the house In my visits to the other cases mentioned I washed my hands, and then wetted them thoroughly with antiseptic cologne No other precautions were used

Theoretically, I ought to have refused to attend the cases of confinement, or one of the cases should have had puerperal fever I think the danger emphasized in Dr MacLaren's article has been exaggerated, and that with ordinary care and cleanliness the obstetrician may continue his attendance on cases of scarlet fever and erysipelas

ALBERT REYNOLDS, M D
(University of Vt 1864)

Clinton, Iowa, August 24, 1887

NECROLOGY

WILLIAM MORROW BEACH

Dr William Morrow Beach was born in Amity, Madison Co, O, May 10th, 1831, and died at his home near London, O, May 5th, 1887, aged 56 years Left at an early age to the care of a widowed mother whose scant means gave him but slight opportunities for an education, his indomitable energy surmounted all difficulties and he reached the front rank among those of professional and general culture A student of Prof Samuel M Smith, of Columbus, O, he was graduated from Starling Medical College in 1853, and immediately entered upon the practice of his profession at Unionville Centre, O In 1855 he removed to LaFayette, O, and in 1865 to the beautiful farm where he continued to live until his death

In April, 1862, he entered the service of the U S Army as Assistant Surgeon, and joined the Army at Shiloh just after the great battle at that place As Surgeon to the 20th O, and later to the 78th O, he

was in June, 1864, commissioned Surgeon of the 118th O and served with that regiment until his muster out in June 1865 In 1869 he was elected, as a Republican Representative in the State Legislature, and two years later was elected State Senator He was an active worker in Medical Societies, having served as President of his County Society, District Society, State Society, and was first President of the State Sanitary Society, he was also a prominent member of the American Medical Association

As a practitioner he was careful and attentive, giving his time and best efforts to his patients regardless of their ability to pay To his brother physicians he was courteous, and to the younger members of the profession particularly attentive Through his industry and ability he amassed wealth, which to him seemed only a means of doing good to others He was possessed of rare amiability, great kindness of heart, and a courtesy that won him many friends

BOOK REVIEWS.

EVACUANT MEDICATION (Cathartics and Emetics) By HENRY M FIELD, M D, Professor of Therapeutics, Dartmouth Medical College, etc 8vo, pp 288 *Philadelphia* P Blakiston, Son & Co 1887 Chicago W T Keener

Dr Field has written a book that may be said to stand alone in medical literature A practical work on the indications, action, application and contra-indications of cathartics and emetics is something that, so far as we are aware, did not exist in medical literature until the appearance of this book Many practitioners have favorite "purgatives" which they are inclined to use indiscriminately Dr Field's little book will be of great value to such, if they study it, as well as to others The book is one of much value, and there is nothing that can take its place The only criticism to be made is that no mention is made of the use of glycerine in combination with castor oil, which, in small doses, is a most valuable evacuant in cases of impacted colon

A LABORATORY MANUAL OF CHEMISTRY, MEDICAL AND PHARMACEUTICAL, containing experiments and Practical Lessons in Inorganic Synthetical Work, Formulæ for over three hundred Preparations, with explanatory Notes, examples in Quantitative Determinations and Valuation of Drugs, and short systematic Courses in Qualitative Analysis and in the Examination of Wine By OSCAR OLDBERG, Pharm D, Professor of Pharmacy and Director of the Pharmaceutical Laboratories in the Illinois College of Pharmacy, etc, and JOHN H LONG, Sc D, Professor of Chemistry and Director of the Chemical Laboratories of the Chicago Medical College and the Illinois College of Pharmacy, etc With original illustrations 8vo, pp 435 Chicago W T Keener

This book is conveniently arranged in three parts, The Elements, Synthetical Chemistry, and Analytical Chemistry The elements are treated of in 78 pages, the necessary information, including tests, being given concisely and clearly In the part on Synthetical Chemistry we find an excuse for quarreling with the authors they do not tell us how to make antipyrin, thallin, kairin and some of the other substances that have been brought out by the attempts to make quinine synthetically The chapter on urine analysis is incomplete But for all this we do not know of a laboratory guide that is better suited for the student, and especially for medical students It contains all that any medical student can hope to learn, with directions how to do it—and very much more than many teachers of medical chemistry know It is *the* laboratory manual for the student—and no one can learn chemistry outside of a laboratory As will be seen, much of the table of contents is given on the title page

BERND'S PHYSICIAN'S POCKET REGISTER Henry Bernd & Co, 2,631 Chestnut St, St Louis, Mo

This is a perpetual visiting list and physician's account book, most conveniently arranged It contains no "dose list" or other printed matter generally found in visiting lists, but as a register, account book and pocket ledger it stands at the head It contains an erasive memorandum tablet, on which the visits to be made during the day may be recorded It is elegantly bound in full seal

MISCELLANEOUS.

CHOLERA IN INDIA —A Reuter telegram from Simla, of August 15, states that in the Northwest Provinces 70,000 persons died from cholera during June and July, but thus far this report has not been confirmed

"EL SEHA" is the title of a monthly Review of Public Hygiene and Medical Science, the first number of which appeared on August 1 The editorial corps consists of Dr H R Greene Pacha, Dr Issa Pacha Hamdi, Dr Mahmoud Bey Sidky, Dr Mahmoud Bey Mustapha, Dr Hassan Effendi Kourchid, Mr J Price, Dr Hassan Bey Rifki, and Ibraham Bey Mustapha

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM AUGUST 27, 1887, TO SEPTEMBER 2, 1887

Lieut Col Joseph R Smith, Surgeon, ordered to report in person to the Surgeon General of the Army, on September 2, 1887, on business connected with the public service, and on completion thereof to return to his proper station Par 9, S O 198, A G O, August 26, 1887

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY, DURING THE WEEK ENDING SEPTEMBER 3, 1887

Medical Director Richard Dean, detached from duty as member of Examining and Retiring Boards, and to Hospital, Chelsea, Mass
Medical Director George Peck, orders as delegate to International Medical Congress revoked.
Surgeon M H Simons, detached from "Constellation," and to the Naval Academy
Surgeon B F Rogers, detached from Marine Rendezvous, New York, and to the "Alliance"
Asst Surgeon James G Field, detached from the "Vermont," and to Marine Rendezvous, N Y
Asst Surgeon C P Henry, ordered to the "Ossipee"
P A Surgeon G P Lumsden, to the "Boston"
Asst Surgeon Louis W Atlee, restored to duty

THE SURGICAL TREATMENT OF SUPPURATIVE PLEURITIS IN CHILDREN

Read in the Section on Surgery and Anatomy, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY A Y P GARNETT, M D,

OF WASHINGTON D C

In the very brief paper which I shall present, it is not my purpose to discuss the history of this disease, its etiology, its pathology, its progress or its general treatment I propose simply to confine my remarks to the comparative merits of the operation of removing the pus by the old method of the trocar and drainage tube, with the more modern one of resecting or excising a portion of one or more ribs, restricting this comparison of the two surgical procedures, to the cases ocurring in children

It is known that as far back as the time of Hippocrates, the operation for the removal of pleuritic effusion, whether of pus, serum or blood, was practiced by the ancients, many crude and imperfect instruments being employed for this purpose, and circumstantial details of all the minutiæ necessary at each stage of the operation laid down by Hippocrates himself Not until 1665, however, we are told, was the ordinary trocar introduced and the operation of draining off the contents of the pleural sac by this means resorted to

It was demonstrated that the supposed danger of introducing atmospheric air into the pleural cavity was and still is, greatly exaggerated, and the consequent employment of the trocar for this operation became more general Scultetus, perhaps the most ingenious and skilful surgeon of his day, invented several instruments for this purpose constructed upon the principle of the trocar, but so arranged as to prevent the admission of air into the pleural cavity He also was the first, so far as I have been able to learn, to use a drainage tube It is not necessary, however, in tracing the history of this instrument in this connection, that I should follow its varying popularity, its triumphs and its defeats through a period of two or more hundred years, we will leave the discussion by its advocates and its opponents, preceding the present half century, and endeavor to present a brief outline of its use during this latter period The late Professor Gross, in the second volume of his "Surgery," after giving in detail minute directions how the operation of tapping the chest empyema should be done, using of course, the trocar, says that of 820 recorded cases but one death occurred by hæmorrhage in this operation, of 498 cases collected by Gunther in 1861, 302 were cured, 149 died, sixteen were improved, nineteen recovered with fistulous openings, and of twelve the result was unknown Of 132 cases reported by Dr Brady, 79 were cured In a number of those which ended fatally irremediable ravages of the disease had occurred before the operation was done and others died of phthisis Dr Blake, of Boston, reported in 1879, nineteen cases operated on by incision as a means of introducing the drainage tube with fifteen recoveries It is very much to be regretted that these cases have not been classified according to age, as the omission deprives us of the opportunity to compare the relative mortality between the adult and the child In view, however, of the advanced and chronic condition of the disease so much more frequently met with in the adult with its accompanying results of extensive bands of adhesion, fibrous deposits and inspissated pus, it is fair to presume that the mortality was largely due to the fact that a majority of those operated upon were adults If, however, with the acknowledged unfavorable conditions found in adult cases, such gratifying results could be obtained by the trocar alone or only partial drainage, how much greater success would have been achieved had these operations been confined alone to children, and if we add the still greater advantage of having used the drainage tube in each case, the result would undoubtedly have been more conclusively successful Before further discussing the advantages of using the trocar and drainage tube over the operation of removing portions of ribs in children, we will refer to the recorded statistics of each of these procedures, embracing *First*, a tabular statement prepared by Dr Godlee of thirty four cases of empyema in children treated at the North-Eastern Hospital, London, including four cases treated at the Brompton Hospital, *Second*, nineteen cases from the reports of St Thomas' Hospital of children under 3 years of age.

Gross somewhere speaks of having operated 150 times by tapping followed by successful results in a majority of the cases, and Dr Henry I Bowditch in a letter recently addressed to me speaks of his last operation by tapping as the 399th In neither of the latter reports have I been able to find that any tabulated statement was ever prepared, giving age, date of operation, specific conditions of each case and results in each

TABLE OF CASES REPORTED BY DR GODLEE

No	Age	Duration	Treatment	Result	No
1	1 year	3 months	Aspirated January 9 1883, 1 pint Jan 23, 6 oz Jan 30, 4 oz Opened Feb 10, behind, rib removed	Death Empyema on opposite side	1
2	1 yr 3 mos	1 month	Aspirated July 11, 1884, opened July 26, part of 8th rib removed behind	Cured in six weeks	2
4	2 years	6 weeks	Opened August 1, 1885, rib removed behind tube out August 13	Cured in four weeks	4
5	2 yrs 4 mos	9 weeks	Aspirated July 4, 1885, opened through abscess July 7, tube removed July 15 Part of 7th rib removed tube put back Aug 7 finally removed Aug 15	Cured in nine weeks	5
6	2 yrs 5 mos	14 days	Aspirated Aug 14 1883 opened, rib removed behind Aug 17, tube removed Sept 1	Cured in five weeks	6
7	2 yrs 6 mos	8 months	Aspirated Feb 9, 1885, opened, rib removed behind, Feb 28, tube replaced twice, counter opening June 17	Left in September, not quite healed	7
8	3 years	2 months	Aspirated Aug 20, 1883, opened August 24 rib removed behind tube removed Oct 2	Practically cured in eight weeks	8
9	3 years		Aspiration failed opened Nov 14, 1883 rib removed behind	Cured in ten weeks	9
11	3 years	5 months	Aspirated Dec 3, 1883, 2 oz, Dec 4 1 oz opened, rib removed behind Dec 7	Practically cured in seven weeks	11
13	4 years		Aspirated Oct 31, 1884, 29 oz, sweet Dec 8, expectorated, 2 oz, fetid opened Jan 25 1885 rib removed behind, pus fetid	Cured in eight weeks	13
15	4 years	2 months	Aspirated Aug 9, 1885 Opened Aug 5 rib removed behind Tube removed Aug 26, put back Aug 31, finally removed Sept 16	Practically cured in five weeks Tube removed too soon	15
3	1 yr 10 mos	3 months	Opened Nov 23, 1881, behind tube out Dec 13	Cured in five weeks	3
10	3 years	6 months	Aspirated Nov 25, 1884, 5 oz very thick pus	Cured by one aspiration	10
12	3 yrs 4 mos	3 months	Aspirated May 12, 1885, 4 oz	Cured by one aspiration	12
14	4 years	3 months	Aspirated April 28, 1884, one syringeful	Cured by one aspiration	14
16	5 years		Aspirated April 7, 1882, 10 oz, April 9, 7 oz Opened April 10 Tube re inserted Sept 9	Practically cured in six months	16
17	5 years		Aspirated July 24, 1883, 4 oz, July 26, 11 oz Opened Aug 12, rib removed behind, tube left out Aug 29	Cured in four weeks	17
18	5 years	1 month	Expectorated two months after commencement of illness	Cured	18
19	5 years	5 months	Part of 7th rib removed and tube put in Feb 17, 1883, left out March 27	Cured in six weeks	19
20	5 yrs 6 mos	2 weeks	Aspirated April 13, opened, 10, rib removed behind	Cured in eight weeks	0
21	5 yrs 6 mos	10 days	Aspirated June 10 1882, 26 oz Opened July 1, 7, interspace, July 7, rib removed, tube left out Sept 2	Cured in fourteen weeks	21
22	5 yrs 6 mos	4 days (?)	Aspirated May 12, 1884, opened 27, rib removed July 13, second opening further back	General health good, but sinus remains Sept, 1885	2
23	6 years	5 weeks	Aspirated Jan 29 1885 subcutaneous rupture near nipple February 7, opened through abscess 6th interspace, no rib	Cured in eight weeks Trouble with tube	23
24	6 years	4 months	Aspirated Jan 10, 1885 opened, rib removed behind, 26th	Small cavity remaining three months	24
25	6 years	4 months	Aspirated Nov 18, 1884	Cured by one aspiration	25
26	6 years	6 weeks	Aspirated July 7, 1885, opened, rib removed behind 17th, tube rem'd 29th	Cured in three weeks	26
27	7 years	3 weeks	Aspirated Aug 24, 1883 27th, 4 oz Sept 1, 9 oz Opened, rib rem'd behind Sept 8, tube left out 20th	Cured in three weeks	27
28	8 years		Aspirated April 10, 1882, opened 21, 7th interspace, no rib	Cured in four weeks	8
29	9 years	9 days	Aspirated May 2, 1882 3 oz, 5th 22 oz, 19th 20 oz Opened 23d, no rib Tube removed July 19	Cured in nine weeks	9
30	10 years	12 months	Opened through abscess in 7th interspace, no rib, March 31, 1883 Pus vomited during operation	Practically healed in seven weeks	30
31	5 yrs 6 mos	5 months	Sept 6, 1883, piece of 6th rib outside nipple removed healed reopened Nov 30	Never completely healed Died afterwards of bronchitis (A very delicate child)	31
32	6 yrs 6 mos	3 months	June 18, 1885, incision	Healed in three months	32
33	7 years	1 month	Aug 27, part of 7th rib removed	Healed on Sept 22 (under five weeks)	33
34	10 years	5 months	Dec, 1883, openings dilated Feb, 1884, parts of 5th, 6th, 7th and 8th ribs removed July 11, several other pieces of rib removed Nov 20, openings into 1st intercostal space	Much improved All closed but a minute cavity, into which a straight celluloid tube 2½ in long was inserted	34

The above statistical table, examined in detail, shows that the ages of those operated upon ranged from 1 year and 3 months to 10 years and 5 months Three under 2 years, four under 3 years, five under 4 years, three under 5 years, eight under 6 years, five under 7 years, two under 8 years, one under 9 years, one under 10 years, and two under 11 years Of the first group one was aspirated three times, no drainage tube used Rib resected at the end of one month, died One aspirated once, no drainage tube, rib resected fifteen days later, recovered in five weeks

Of the second group one was resected and cured in four weeks, three were first aspirated, no drainage tube, subsequently resected and recovered Of the third group, three were aspirated, no drainage tube use, finally portion of rib removed, followed by recoveries, two were cured by one aspiration Group four shows that all three were aspirated, followed in two of them by excision of rib, with recovery in all three cases Of the seven cases included in the fifth group, five were first aspirated, no drainage used, followed by removal of ribs in each case, resulting in cures The remaining two were subjected to resection of ribs without being previously aspirated, also resulted favorably The sixth group included four aspirations, no drainage tube in either case, subsequent resection of ribs with three cures and one partial success Group seven embraces but two cases, one aspirated before the resection was performed, and the other rib excised at first operation, both cured The eighth and ninth groups including one case each, both aspirared at first, but subsequently opened by incision and drainage tubes inserted, one recovered in four weeks and the other in nine weeks The tenth group numbers but two cases, one cured by pleurotomy and drainage tube, the other greatly benefited by extensive resection of parts of the fifth, sixth, seventh, and eighth ribs, but not reported as cured It thus appears of the thirty one cases reported as cured in this table, twenty five were subjected to the antecedent operation of aspiration, and six to primary resections Four of the twenty-five were cured by one aspiration alone, the remaining twenty-one were all subsequently treated by removal of one or more ribs It will be observed that in all the cases in which resection was practiced, the drainage tube was inserted and retained, as a rule, until the cure had been completed Had such a plan been adopted in the first instance, when the operation of tapping was performed, it is more than probable that not one of the twenty-one children so treated would have been subjected to so grave and hazardous an operation as excision of the ribs The four cases of recovery by one aspiration alone goes to demonstrate the conservative capacity of nature when left in a large degree, to her own resources, as well as the energetic and active process of absorption going on in childhood

An analysis of this table shows that all but one of these cases were subjected to the operation of tapping before excision of the rib was resorted to In one case four antecedent tappings, two cases of three tappings, two cases of two tappings, and nine having been tapped but once As it was found

THE RESULT OF EXCISION OF A PORTION OF RIB IN FIFTEEN CASES OF EMPYEMA, FROM ST THOMAS' HOSPITAL REPORTS, LONDON

No	Age	Tapping before Operat'n	Side	Tube used before Operat'n	Chronic Fistula	Ab Callus	Result
1	5½ male	4	Left	None	None	None	Cured
2	5 "	None	"	"	Yes		No benefit
3	5 "	1	"	"	None	"	Cured
4	13 "	1	Right.	"		"	
5	31 "	1	"	"	Yes	"	Working (CPk)
6	13 "	3	Left.	"	None	"	Cured
7	44 "	2	"	"		"	
8	58 "	1	Right	"	Yes	"	Died
9	19 "	1	"	"	None	"	"
10	24	3	"	"	Yes.	"	Some benefit
11	20	2	"	"	None	"	Cured
12	23	1	Left	"	"	"	
13	25 "	1	"	"	"	"	"
14	34 "	1	"	"	"	"	Died
15	23 Female	1	Right	"	"	"	Cured

Remarks—Drainage tube was used in all cases after excision of rib The average stay in hospital was 185 days

necessary to perform the operation of resection of one or more ribs subsequently, it is fair to suppose that the prior operation of tapping had failed to effect a cure Of the whole number operated on 9 were cured, 3 died and 2 only benefitted It will be observed that in all these 15 cases in which a portion of the rib was removed, drainage tubes were introduced, but in not one case in which tapping alone was practiced did the operator introduce a drainage tube, had this been done (which can always be easily effected by the use of a large trocar or enlarging with a bistoury, the opening made by the trocar), and the pleural cavity kept drained of its contents, the same favorable results would have followed and the more extensive and dangerous operation of resection been found unnecessary In children it is rarely we find more than a single cyst, and when diagnosed in the early stages, more frequently contain serum than pus, hence the facility with which cures may be effected in such cases, sometimes by one or two aspirations only, but more surely when the drainage tube is used, to avoid a reaccumulation of the fluid and allow a speedy expansion of the lung This, however, is not always the case, we sometimes meet with instances of pure purulent pleurisies in children where there has been no antecedent accumulation of serum or exudation of lymph upon the serous lining of the cavity, pus has been secreted from the very commencement of the attack and the cavity most usually in such cases found to be well filled It has not been found that these conditions are associated with tubercular contaminations, but in those who are free from such hereditary tendency In advocating the superiority of the trocar with drainage tube for the removal of these accumulations over the operation of resection of ribs, the following considerations present themselves to my mind as furnishing satisfactory reasons for such a preference

First, as above stated in children the fluid is most frequently found occupying a single sac or cyst being

of recent date The conditions found to exist in chronic cases, such as fibrous bands, pouches, sacs, forming numerous isolated cavities, inspissated pus, thickened pleuræ, etc , are absent The compressed lung tissue has not undergone any parenchymatous changes affecting its natural elasticity, the mechanical pressure of the fluid being removed it readily resumes its normal capacity The surfaces of the pleural cavity not having experienced those pathological changes usually found in chronic pyogenic membranes and the functions of absorption being more active in children, the partial removal of the contents of the sac by aspiration alone may give an increased impetus to that function and establish a cure by absorption

It may be that the stimulus of atmospheric air plays some part as a conservative agent in adding energy to this process Godlee, who it seems resorted to the operation of excision, in all of his cases, as reported in the table which I have quoted above, acknowledges in one of his papers that the operation of tapping children is often successful and recommends that in young subjects it should always be done at first and two or more tappings resorted to if necessary, before the graver operation of excision of rib be performed He, however, fails to advise what in my judgment constitutes almost a *sine qua non* to early success in all these cases of tapping, the additional use of drainage tube The objection which has been urged against this operation in children, namely, that the space between the ribs does not admit of using a trocar of sufficient calibre to accommodate a large sized tube and that it is almost impossible to keep the sinus or opening patulous for any length of time presents, to my mind, no significance, since the experience of those who practiced this operation through a long series of years, furnishes a positive contradiction to this criticism

Every surgeon knows that such a difficulty can always be overcome by enlarging the opening with a common bistoury In support of these views I here introduce the letter already referred to, of Dr Henry I Bowditch, of Boston, who has perhaps performed the operation of tapping the chest oftener than any other man now living He says

"For thirty-seven years I have been using the exploring trocar and suction pump in cases of pleuritic affection Sometimes repeatedly in the same person, and generally with success if the patient has been seen early enough Years since I began in several cases to make permanent openings by means of a large trocar and canula, the latter being left in the opening I have injected, at times, simple warm water (would it not be well under modern antiseptic ideas to use almost hot water?), I have injected repeated syringefuls *until the water was returned apparently free of pus*

"Generally, however, I have made no injection, if the patient with the free discharge has been improving

"Exsection of a rib I have never deemed necessary in childhood, nor in adults when the patient has been seen early enough to be able to try the above operations, one or both, without success I have advised it with advantage, in some cases, of adults Like everything else that is good in this world, it has been at times of late used most inappropriately and extravagantly as in one of my own cases, while the patient was traveling in Europe and with death as the result Nevertheless, I believe that used cautiously it will be of great advantage in certain chronic cases

"As I have never seen a case in childhood where I have felt called on to advise exsection, so I feel indisposed to advise it now, if any other course promises success

"I am sorry that I can not give you any more detailed statistics In a general way I will say that I made my last operation (399th), on my 256th patient, Aug 25, 1886 "

It will be observed that this experienced and eminent surgeon fully endorses the views which I have endeavored to present in this paper He says exsection of a rib I have never deemed necessary in children With a record of 390 operations, a large proportion of whom were children, his judgment on this point is not only entitled to our respect but should be regarded as conclusive Excision of a portion of one or more ribs for empyema as a substitute for, or supplementary to, the operation of tapping is a surgical procedure of comparatively modern date, although it has been claimed that it was first suggested, if not performed, by Celsus In this country I believe that Dr Warren Stone, of New Orleans, was the first to do the operation Estlander, of Helsingfors, seems to have directed more general attention to this practice and extolled its peculiar merits So far as I have been able to learn by reference to the recorded views of many distinguished surgeons of modern times, no distinction is made by them who advocate the operation of resection, between adults and children, perhaps, more frequently performed in cases of the latter than the former So far indeed as the statistics of hospital practice within the last decade show, the rule has been to operate by resection in all cases of children

As I have above stated in discussing the superior merits of tapping the conditions most usually met with in young children differ so materially from those encountered in the chronic cases of the pleuritis of adults, that I think age should be regarded as a factor of primary importance in determining the exact diagnosis as well as selecting the particular mode of surgical interference When we consider the fact that the bony fabric of the chest in the child is still in a condition of progressive physical development, the rapid and excessive deposit of callus following the solution of continuity of a rib, protruding into the cavity of the chest and irritating the lung, the inevitable deformity and loss of symmetry in expansion of the two sides of the thorax, which is apt to follow the removal of one or more ribs, the growing condition of the child which necessarily adapts itself to the physical results of the traumatic interference, establishing often a permanent deformity, associated at times with more or less spondylitis, and a greatly restricted respiratory capacity of the chest, the

pouch of periosteum from which the excised piece of rib has been dissected, the protracted healing and long continued dressing of the open wound, augmenting the chances of septicæmia and exhausting the vital energies and recuperative resources of the little sufferer We should hesitate before resorting to so grave a surgical procedure when a more simple and conservative one can be safely and successfully practiced

In presenting the above criticism upon the operation of resection or removal of one or more ribs for the cure of empyema it will be remembered that I have reference to the operation upon young children exclusively, having in view simply a desire to call attention to the importance of discriminating carefully in the surgical treatment of these cases between adults and children

Jacobi says "Excision of the ribs should never be practiced in children "

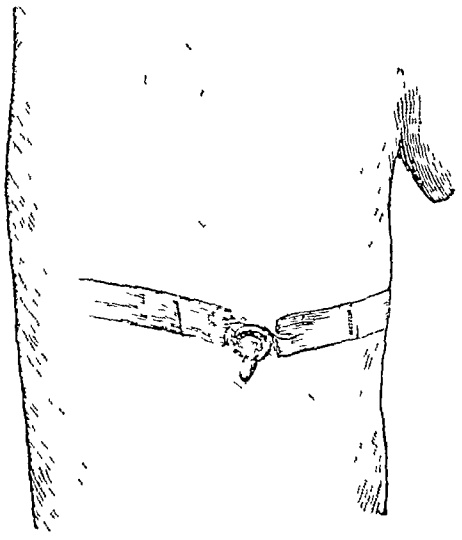
J Lewis Smith says "That he never could conscientiously recommend excision in any case in his practice, hospital or private "

T Clifford Albutt says "Resection of a portion of two or more ribs may be necessary in some cases, but such cases will become very rare as diagnosis and early operative relief are more generally understood " If I deemed it necessary I might add the testimony in support of my views upon this subject, of many other experienced and skilful surgeons The following brief notice and accompanying photograph of a case upon which I operated some three years ago will serve to illustrate the simple but effectual procedure advocated in such cases

This youth was sent to me from the country supposed to be far advanced in phthisis Had suffered for six months with symptoms of tubercular consumption including expectoration of large quantities of pus A careful physical examination revealed the presence of empyema of right chest, pleural cavity well filled with pus, and lung compressed against spinal column I decided to tap him at once with a medium sized trocar, which was done through the sixth intercostal space, and about 32 oz of pus drawn off The cavity was not washed out nor was a drainage tube inserted Great relief was afforded the boy and the cough almost entirely suspended

In three weeks the pleural sac had refilled entirely with pus, all of the distressing symptoms returned and the patient and friends despondent I now determined to repeat the operation of tapping with a large trocar, and introduced a soft rubber tube At this operation nearly the same amount of pus was drawn off and after the cavity had been washed out with tepid water the tube was inserted and kept in its place by the device represented in the picture A large piece of soft sponge moistened with carbolized water was placed so as to allow the end of the tube to rest on it and confined by a bandage, no antiseptics used

Each succeeding day the cavity was washed out with tepid water, at first nearly one quart being used In three weeks the cavity had so diminished by the expansion of the lung that but 1 oz of fluid could be thrown in, and at the expiration of four weeks the tube was removed and the sinus allowed to heal The patient continued to grow fat and strong and is now perfectly well In this connection I may refer to the mooted question of using injections after drawing off the contents of the cavity Many surgeons object to their use while others employ them Dr Cayly, of England, reports many cases of sudden death resulting from injections of simple water, solution of iodine and of carbolic acid In all of which death occurred after repeated injections had been used with apparent impunity As no explanation of the cause of death in such instances has been offered, and as the practice of using tepid water has been so generally and safely employed I can see no rational grounds for entertaining such apprehensions



UTERINE SUBINVOLUTION AND AREOLAR HYPERPLASIA

Read in the Section on Obstetrics and Diseases of Women, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY JOSEPH EASTMAN, M D ,

PROFESSOR OF GYNECOLOGY, INDIANAPOLIS IND

Physiologically considered, the uterus is more subject to variations in size than any other organ of the human body "Its weight, but little more than one ounce in the virgin state, increases during pregnancy to upwards of two pounds After labor, in two days it falls to a pound and a half, during the first week to one pound The cell elements are consumed, compression of nutrient blood-vessels cuts off fresh supplies from the oxidized protoplasm, and in from six to eight weeks the uterus is reduced to almost its normal proportions " If this tearing down and carrying away, by nature's forces, that structure which enveloped the child and nourished it during the period of intra-uterine existence, stops short of completion, we have the condition known as subinvolution or arrested retrograde evolution

Pathological Anatomy—Edis says "In the early stages of subinvolution following parturition, hypertrophy of the muscular structure equally with that of the connective tissue may be found, but later on, in the large majority of cases, on microscopic examination, the amount of fibrous tissue predominates over the muscular fibre Within a few days after parturition, the fully developed muscular fibres undergo a fatty degeneration, the fatty globules being absorbed and the uterus thus rapidly diminishes in size and weight" Should any cause retard or check this process, the uterus will remain flabby and large Thomas says "At first the tissues are infiltrated with serum In process of time the uterine walls diminish in size, their tissues grow less vascular, the blood-vessels become smaller, and the uterine cavity assumes smaller dimensions, but the organ does not assume its original size It remains large, dense, firm and sensitive for years, presenting the characteristic appearance of the so called parenchymatous metritis Cases which were formerly regarded as examples of inflammation on account of the existence of enlargement, congestion, and tenderness upon pressure, the microscope now *proves* to have been instances of excessive growth of connective tissue of the uterus, with resulting hyperæsthesia of its nerves"[1]

Klob states that diffuse growth of connective tissue constitutes the so called induration hitherto considered as a result of parenchymatous inflammation of the uterus

Has every congested, voluminous, tender and displaced uterus once contained an embryo or fœtus? Let us reason, that for from 25 to 35 years, the virgin uterus is subject to monthly enlargement and shrinkage, differing little, except in degree, from what occurs in the multiparous organ The nervous system, especially the uterine plexus, is in a state of hyperæsthesia during menstruation, while the vascular supply, physiologically great, needs only to be disturbed by one or more causes, mental or physical, to produce blood stasis, followed by hypergenesis of connective tissue—precisely the pathological condition present in a vast majority of all chronic uterine disorders Menstrual subinvolution is, then, worthy of consideration in this connection

It has been shown that the position of the uterus varies widely within normal limits It should also be borne in mind that "nidation and denidation," together with the vascular changes constantly taking place in the uterine mucosa, make it clear that the uterus has no permanent size, enlargement and shrinkage being the law of its existence during menstrual life Hence there are many cases of so-called chronic inflammation not directly traceable to childbirth, and others in no way connected with it at all

I further quote Prof Byford "The circulation of the uterus is increased in quantity from the cessation of one flow till the beginning of the next During the days of the flow the afflux of blood subsides to the lowest amount From the cessation of the monthly flow there is an increase of solid tissue in the uterus until the beginning of the next flow, during which time there is involution, or an elimination of solid tissue, notably the mucous membrane of the cavity These processes of afflux of blood and *accessions of tissue may be and often are prolonged and pass into what is known* as *congestion* of the uterus" Again he says "In both menstrual and post-partum subinvolution this simple vascular condition does not continue for any great length of time Hyperæmia is often a *mischievous condition*, and sooner or later causes changes in the organization of the viscus in which it exists" In subinvolution there is at first hyperæmia with hypertrophy of the fibrous, vascular, and nervous tissues These solid portions of the organ degenerate, not into fatty substance that may be absorbed, but into fibrous tissue of a low organization Subinvolution is a term, then, which embraces different pathological conditions, or perhaps it would be expressing the facts better to say that several distinct pathological conditions of the uterus result from subinvolution This last statement will apply equally to menstrual and post partum subinvolution

Etiology—Emmet, in the second edition of his book, dismisses the subject of subinvolution with the statement that he has for many years found few or no cases of subinvolution not due to laceration of the cervix In the third edition, in speaking of "Lacerations and their Treatment," he says "A careful study of the history of the cases which have passed under my observation during the past five years, and have finally required operations, teaches, if anything, that a laceration of the cervix, however extensive, will rapidly heal without an untoward symptom unless blood poisoning should take place This occurrence is always accompanied by some general disturbance, and is marked by a septic cellulitis which obstructs the pelvic circulation so as to arrest involution and repair of injury" He then adds "If this is proven it becomes a question as to how far the necessity for a subsequent operation, to repair the injury, may be limited or rendered unnecessary by the early care of the obstetrician"

I have seen fit to place this quotation under the head of causation, that it may aid in determining the relation of cause and effect between the arrested involution and the laceration Emmet has given us the link, that was missing in his former editions, between the cause—laceration—and the effect—impaired health of the patient This missing link, this arrested involution, is a factor prominently presented by this great master as worthy of consideration in connection with the operation for closing a laceration In another place Emmet (2d ed) gives us to understand that subinvolution may have constitutional causes He says "We will find, as a rule, feeble respiration in both lungs, with an increase of secretion throughout the air passages, the condition being best fitted for the rapid development of tubercle" Again he says "This perverted state of the mucous membrane is, equal with subinvolution, an indication of some serious defect in nutrition" Low states of nutrition are among the predisposing causes, such as are found in prolonged nervous depression,

[1] Winckel's late work, by Prof Parvin, treats this subject under the head of Chronic Metritis

grief, worry, etc , among the exciting causes, partu rition oft repeated, opium to stop after-pains, which are but signals that nature is starting up healthy in volution, and expelling clots Further, opium hinders retrograde metamorphoses and lessens secretion Want of stimulation to contraction from nursing child, or still birth, to which latter may be added grief, or over exertion, or insufficient exercise following parturition, may be added The uterus should contract by a vital force, such force not being obtainable by inactivity

Torpid conditions of the liver and intestines, interfering with the return of blood from the pelvis through the portal veins, abdominal tumors pressing on the vena cava, septic instruments used by physicians, such as sound, etc , unskilful manipulation of same, displacements, and as Klob states, its cause must be sought for in habitual hyperæmia Emmet speaks of having found congestive hypertrophy of the uterus in ladies who have lived in malarious districts, especially the Southern States This enlargement remained as a sequel of repeated attacks of remittent fever The venous congestion of the pelvis and enlargement of the uterus were brought about after the muscles had lost their tone from the constant obstruction to the return of the circulation through the portal system

Parturition may act simply as a predisposing cause As Thomas states, a woman has a child, has no postpartum trouble and goes through involution perfectly A year or two later she has endometritis This in time produces areolar hyperplasia with its usual symptoms and physical signs, the same kind and degree of endometritis in a virgin would have lasted for years without parenchymatous complication In the former case the endometric disease existed on ground as favorable to hyperplasia because an important predisposing cause existed In the latter case such predisposition was wanting

To illustrate more clearly how causes other than parturition may produce hyperplasia, I will give two examples taken from observation

Case 1 —A lady with a perfectly healthy uterus being in great anxiety to prepare for a journey, neglected to evacuate the bowels for several days, puts on a tight corset dragged down by several heavy skirts, makes her journey, but before leaving the warm car does not empty the bladder, the excretion of urine is increased by the chilling carriage ride The distended bladder pushes the fundus of the uterus backwards The distended rectum pushes the cervix forwards, and, as she alights from the conveyance, the uterus turns backward into the hollow of the sacrum, its more complete impaction being insured by running up a flight of stairs or even high steps Menstruation, which was due at this time, is delayed She has pain, and becomes an invalid A year later she is found to have complete retroversion with areolar hyperplasia, innervation, circulation and nutrition of the uterus having been deranged by the displacement

Case 2 —A lady of feeble nutrition and circulation, by exposing and chilling the body near her menstrual period, has a leucorrhœal discharge which soon changes the normal chemical reaction of the cervical and vaginal secretions, the discharge becoming irritating, bathing the vaginal face of the cervix and denuding it of epithelium, and subsequently of mucous membrane The Nabothian glands become swollen, the cervix, internal and external, granular These raw surfaces admit of the absorption of septic material, which in time produces uterine and pelvic congestion Each recurring menstrual period leaves the uterus a little larger than before, until continued hyperæmia results in areolar hyperplasia with displacements, menstrual disorders and all the symptoms, subjective and objective, found in subinvolution

Diagnosis —This requires skilled efforts and great dexterity in conjoined manipulation The clinical history of no two cases will be the same The morbid phenomena are frequently referable to the origin of the disease The subjective symptoms will include dull, heavy, dragging pain through the pelvis, much increased by locomotion, dull pain beginning several days before menstruation and lasting during that process, pain in the breasts before and during menstruation, darkening of the areola of the breasts, nausea and vomiting, great nervous disturbance, pressure on the rectum with tenesmus and hemorrhoids, pressure on the bladder with vesical tenesmus, menstrual disorders and sterility

Physical Signs —If the disease be limited to the cervix, it will be found large, swollen and painful, the os patulous On conjoined manipulation the cervix is found to be unduly sensitive, especially if it be lifted up by the finger There is usually some leucorrhœa or granular degeneration present In the early stage of subinvolution there is softness of the tissues, which is less noticeable in the more advanced forms of hyperplasia Where the body of the uterus is involved, on conjoined manipulation the organ is found to be much enlarged, the thickness of the walls being greater than the increase in length The uterus is lower in the pelvis and less movable than normal, from its intrinsic bulk, and is more sensitive to pressure than in health The displaced uterus is often complicated with prolapsed and tender ovaries

From the foregoing symptoms it will be seen that it would be no easy task to differentiate between subinvolution and early pregnancy, especially if the patient be yet a nursing woman, and no evidence could be gained by a return of the menstrual flow The skilled hand ought to be able to detect the more globular shape of the uterus and the feeling of tension suggestive of a contained fluid Nausea, pressure on the neck of the bladder, irritation of the breasts, etc , are often as well marked in subinvolution as in pregnancy, and therefore aid little in differentiation Even a discharge of blood once a month may come from an abrasion on the neck of the uterus

As between beginning fibroid tumors the differentiation is extremely difficult, especially if they are the same, except that in fibroids we have a local, in subinvolution a diffuse hyperplasia of connective tissue

Prognosis — This will depend upon the general condition of the patient, what she will submit to, and

the extent of the replacement of normal muscular tissue by the abnormal connective tissue

Treatment—Keeping in mind the fact that this condition is not inflammatory, but one of debility, in the vast majority of cases, the importance of constitutional treatment is self-evident The most perfect state of secretion and excretion possible should be secured and maintained, to the end that the highest degree of assimilation and nutrition shall furnish plenty of blood, rich in red corpuscles, to aid in ridding the uterus of its redundant fibrous tissue The full, free expansion of the lungs by atmospheric pressure, uninterfered with by corsets or heavy skirts, is absolutely essential to keep the blood pure A sufficient amount of muscular movement is required to keep the blood in circulation through the capillaries, especially of the skin

If the patient cannot go out riding or walking each day, opening the windows and doors while the patient is warmly covered, as suggested by Prof Byford, will do much to maintain good respiration The preparations of iron, strychnine, ergot, quinine, etc, are of great benefit in most cases

Local Treatment—So high an authority as Emmet declares that he "has seen few cases of subinvolution not due to laceration of the cervix" Admitting the truth of this statement, the important question would be, What relation does the closure of a laceration bear to the cure of the patient? It must not be forgotten in this connection that we have precisely similar pathological conditions in uteri that have become normal in size after delivery and again enlarged from one or more causes which produce dilatation of the pelvic veins, and even in women who have not borne children at all, I often find it necessary to sew up a torn womb, even to cut away a considerable amount of tissue to get rid of the hyperplastic conditions and cicatrices At the same time, *let me insist*, the operation is but one of several factors in the cure, and that, as an etiological factor and therapeutic necessity, it has been over estimated and often abused

Emmet (3rd and last ed) says "The simple existence of a fissure in the cervix does not justify an operation for its closure Nor should the operation be ever resorted to except for the relief of symptoms which have remained after the accepted treatment has been employed without benefit" Again he says "The operation has been performed too often, when no necessity for doing it has existed It has been done quite as often without the proper preparatory treatment, even while more or less cellulitis existed, and still oftener with no clearly definite purpose in view The result has been frequent disappointment, and not seldom the patient has suffered a great impairment of health He also further states that it is necessary to give the preparatory treatment for the reduction of the *cellulitis* and the *rolling* in again of the tissues before it is safe to operate, and before we can even determine the need of performing it If the operation for closing the laceration is performed after the different sources of irritation have been removed, the uterus will be reduced rapidly in size, and the patient will not only regain her health, but remain in the full enjoyment of it afterwards"

From these sensible statements, coming from the originator of the operation, I infer that the pelvic congestion and subinvolution are to be removed, as far as may be, before we *are warranted in operating* Here again the pendulum of science, swung to extremes by a half mania for sudden cures, finds its equipoise on the *terra firma* of *sound surgical principles* Do the best we can, operate as *perfectly* as possible, and even then, in my experience, after treatment, by supports and dilating, is sometimes necessary If this be proven it explains why we see and hear of so many women who have derived little or no benefit from an operation which they were told would cure The wisdom we display in adapting our remedies, whether they be operations or drugs, to the particular stage of the disease, will determine the measure of our success When the uterus is much enlarged, intra-uterine medication, to act upon the excessive mucous membrane, will often do good, the cervix must be well dilated, so that if fluid is to be expelled it will escape through the cervix and not the Fallopian tube, the dilating doing as much good as the medication Churchill's tincture of iodine, nitrate of silver and hot antiseptic vaginal injections are precious remedies in pelvic diseases Let me insist, however, their use requires a wise discrimination

A slight subacute inflammation in the neighborhood of the uterus, involving possibly some of its ligaments, may cause a slight prolapse or displacement A prolapsed ovary, a diseased Fallopian tube, a painful urethral caruncle, or even a fissure in the rectum, may so constantly irritate the pelvic nerves as to disturb innervation and circulation and produce uterine and pelvic congestion, which nature nine times out of ten would attempt to relieve by discharge of blood from the uterine mucosa, or of mucus or pus from the Nabothian glands in the cervix These discharges being but the local expression of some morbid condition, their arrest by local applications is irrational True, the patient may feel better for a time, as arrested outflow increases pressure, disturbs nutrition and facilitates hypergenesis of connective tissue, with its scanty blood supply and few nerve filaments

Practitioners will never secure a few simple means of curing all the diseases found in such complicated structures as the human eye or woman's pelvis—remedies such as shall be universal in their application regardless of the intricacies of diagnosis Such local means as deplete the distended veins and swollen glands will do good Bennet's nitrate of silver being followed by a free discharge of blood on the second day, and stimulating uterine contraction, did good, he thought he cured ulceration and inflammation Simpson and Sims, splitting the cervix, drained out the enlarged veins, securing better uterine nutrition by local depletion The depletion attendant on an operation for closing a lacerated cervix is sometimes the measure of its benefit to the patient Hodge, with his pessary, corrected malposition, restored normal circulation to the pelvic organs, and cured many a sufferer Any displacement must be rectified in order to restore normal circulation, without which

normal innervation and nutrition are impossible For more than two years I have substituted tampons of wool for those of cotton, for the former, by elastic pressure, replace organs better, relieving pressure irritation, and removing many reflex phenomena, thus doing vast good by local *depletion* and local *compression* These should always be applied in a *definite* way and for a *definite* purpose, and if made antiseptic may remain for several days

Vaginal injections with a Hilderbrandt's douche, which enables a competent attendant to use water 10°–15° hotter than can be borne by the external parts, is of decided benefit Rapid, free and repeated dilatation with graduated steel sounds and dilators will, by pressure, excite absorption of the abnormal tissue not only of the cervix, but in the body of the uterus as well The antagonistic action or law of uterine fibre, as laid down by Savage that dilating the cervix causes contraction of the fundus, and *vice versa*, suggests that dilating is a valuable means The lesson learned by dilating hypertrophied anal sphincters can be utilized in treating uterine hyperplasia

The great sheet anchor is electricity The constant current, employing 12 to 30 cells, used every third or fourth day, I consider most valuable Mr Rietz, an eminent electrician of Indianapolis, asserts that no current is constant and steady unless the plates are constantly in the fluid The wonderful results being attained at the present time with electricity in treating fibroids, together with the similarity between hyperplasia and fibroids, lead me to think that electricity, used in the earlier stages of the former, would many times prevent the growth of the latter, and restore many enlarged, tender and displaced uteri to their normal conditions Removal of the ovaries for the cure of subinvolution has been suggested It was not my purpose, however, to speak of the surgical treatment of subinvolution, so much as to call attention to importance of obviating the necessity for surgical operations by removing those morbid pelvic conditions which tend to make such operations necessary

Conclusions —From the foregoing statements bearing on menstrual and post partum subinvolution, I feel warranted in submitting the following questions for discussion

1 Where does subinvolution end, or areolar hyperplasia become sufficiently circumscribed to receive the name interstitial fibroid?

2 Are not all varieties of fibroid tumors but localized conditions of more diffuse areolar hyperplasia?

3 Do not microscopists agree that the areolar hyperplasia of arrested involution and fibroid tumors both originate in uterine hyperæmia?

4 If this be true, does it not suggest that greater efforts to prevent uterine hyperæmia from resulting in hyperplasia, would also lessen the frequency of fibroid tumors?

5 Is not chronic areolar hyperplasia at the foundation of a large number of cases of diseased and displaced uteri and ovaries, and will not any means, medical or surgical, looking to a cure, which does not remove this abnormal tissue, fall short of the desired result?

6 Despite recent advances in gynecic surgery, is not blood, deficient in quantity and quality, as important a *primary* factor in the causation of uterine disease as when Holy Writ first declared, "The blood is the life thereof?"

7 So many new things are becoming old, I present this paper to aid some old things in becoming new, and for the purpose of calling attention to a few points in uterine pathology and therapeutics which, if less frequently forgotten by the average practitioner, would render operations for lacerations, diseased ovaries and other pelvic diseases much less frequent, and of more benefit to women when performed

THE CHEMISTRY OF TYROTOXICON

Its Action upon Lower Animals, and its Relation to the Summer Diarrhœas of Infancy

Read in the Section on State Medicine, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY VICTOR C VAUGHAN, M D, Ph D,

PROFESSOR OF PHYSIOLOGICAL CHEMISTRY IN THE UNIVERSITY OF MICHIGAN AND MEMBER OF THE MICHIGAN STATE BOARD OF HEALTH

Since making my report on the investigations concerning the nature of tyrotoxicon, (report of *Proceedings of the Michigan State Board of Health*, October, 1886), I have continued my work, aided greatly by Messrs F G Novy and E V Riker We soon ascertained that if some butyric acid ferment be prepared as is ordinarily done in the preparation of butyric acid, and some of this be added to normal milk, and the whole be kept in closely stoppered bottles for eight or ten days, the poison will be developed in the milk in considerable quantity The milk should be filtered, the filtrate neutralized with sodium carbonate, and then extracted with ether

Having a strong solution of the poison in absolute alcohol, which had been obtained from milk inoculated as stated above, I added to it some platinum chloride and began to evaporate on the water bath As soon as the alcohol evaporated the residue exploded with great violence The vessel, a glass evaporating dish, was broken into fine fragments and these were scattered over the room, while the gas-light under the water bath was extinguished The experiment was repeated a number of times with like results From some of this alcoholic solution the platinum was removed with hydrogen sulphide gas, but the filtrate was then found to have lost its explosive property This reminded us that diazobenzol compounds form with platinum chloride a highly explosive compound, and that diazobenzol is also decomposed by hydrogen sulphide Some diazobenzol nitrate was prepared according to the method of Griess,[1] and comparisons made between this and tyrotoxicon With equal parts of sulphuric acid and carbolic acid the prepared diazobenzol

[1] Annalen der Chemie und Pharmacie B 137, S 39.

nitrate gave a green coloration, while with the same reagents, tyrotoxicon gave a color which varied from a yellow to an orange-red But the diazobenzol nitrate dissolved in the whey of normal milk, and extracted with ether or in the presence of other proteids, gave the same shades of color as the tyrotoxicon did, and the potassium compound of tyrotoxicon prepared by the method to be given later produced the same shade of green as did the artificial diazobenzol This color test may be used as a preliminary test in examining milk for tyrotoxicon It is best carried out as follows Place on a clean porcelain surface two or three drops each of pure sulphuric acid and pure carbolic acid This mixture should remain colorless or nearly so Then add a few drops of the aqueous solution of the residue left after the spontaneous evaporation of the ether If tyrotoxicon be present a yellow to an orange-red will be produced This test is to be regarded as only a preliminary one, for it may be due to the presence of a nitrate or nitrite [2] The tyrotoxicon must be purified according to a method to be given further on before the absence of nitrate or nitrite can be positively demonstrated

In the filtrate from milk which is rich in tyrotoxicon, after neutralization with sodium carbonate, filtration and acidifying with hydrochloric acid, gold chloride produces a precipitate, which is insoluble in water, but soluble in hot alcohol, from which it separates on cooling in golden plates Diazobenzol compounds give with gold chloride a precipitate having all these properties In both cases the gold compound is decomposed by frequent treatment with hot alcohol, and this fact prevented any satisfactory ultimate analysis of this salt It should be remarked here that from some samples of milk this gold salt is obtained much more easily than from others, and the difference is dependent not so much upon the amount of tyrotoxicon present, as upon the condition of the other organic matter present It is best obtained from samples which have stood in well stoppered bottles for a month or longer Tyrotoxicon obtained from milk was treated according to the method recommended by Griess[3] for the preparation of diazobenzol potassium hydrate, and the per cent of potassium in the compound obtained was determined The filtrate from the milk which had been inoculated with the ferment and kept in a stoppered bottle in a warm room for 10 days, was neutralized with sodium carbonate, agitated with an equal volume of absolute ether, allowed to stand in a stoppered flask for 24 hours, the ether removed and allowed to evaporate from and open dish The aqueous residue was acidified with nitric acid, then treated with an equal volume of a saturated solution of potassium hydrate and the whole concentrated on the water bath On being heated the mixture became yellowish brown, and omitted a peculiar aromatic odor Both the color and odor corresponded exactly with the color and odor produced by carrying some of the artificial diazobenzol through a comparative test On cooling, the mass crystalized, the resulting compound appearing in the test with the tyrotoxicon, and in the comparative test also, in beautiful, six sided plates, along with the prisms of potassium nitrate The crystalline mass obtained from the tyrotoxicon was treated with absolute alcohol, filtered, the filtrate evaporated on the water-bath, the residue dissolved in absolute alcohol, from which it was precipitated in a white crystalline form with ether The precipitate was collected, washed with ether, dried, and the per cent of potassium estimated as potassium sulphate 2045 gram of the substance yielded 109 gram of potassium sulphate Per cent of potassium calculated, in $C_6H_5N_2OK$ 24 42, found, 23 92 This analysis establishes the identity of tyrotoxicon and diazobenzol Chemists will now appreciate the great difficulty that has been experienced in isolating the active agent of poisonous cheese

The readiness with which diazobenzol decomposes is well known When warmed with water it breaks up into carbolic acid and nitrogen Hydrogen sulphide decomposes it, therefore, all attempts to obtain the poison by precipitating it with some base, such as mercury or lead, and then removing the base with hydrogen sulphide, have failed Moreover, diazobenzol is only a transition product of putrefaction I have frequently found that leaving some milk rich in the poison in an open beaker for 24 hours would be sufficient to destroy the whole of the poison We know nothing positively concerning the acid with which diazobenzol is combined in the milk or cheese We prepared some diazobenzol butyrate, $C_6H_5N_2C_4H_7O_2$, and ascertained that the crystals of this compound correspond with those of tyrotoxicon, and that they decompose in moist air with the same rapidity This is the first time that diazobenzol has been found as a product of putrefaction, and it is possible that many of its allied compounds may be formed in the same way

The following experiments will show that the effects of tyrotoxicon and diazobenzol upon the lower animals are identical

Experiment 1 —From one half gallon of some milk, which had stood in a tightly stoppered bottle for three months, there was obtained quite a concentrated aqueous solution of the poison after the spontaneous evaporation of the ether Ten drops of this placed in the mouth of a small dog 3 weeks old caused within a few minutes frothing at the mouth, retching, the vomiting of frothy fluid, rapid breathing, muscular spasm over the abdomen, and after some time watery stools The next day the dog seemed to have recovered partially, but was unable to retain any food This condition continuing for two days, the animal was killed with chloroform No examination of the stomach was made

Experiment 2 —Tyrotoxicon obtained from poisonous ice-cream was given to a cat Within ten minutes, the cat began to retch and soon it vomited The retching and vomiting continued for 2 hours during which time the animal was under observation, and the next morning it was observed that the cat had passed several watery stools After this,

[2] The coloration with nitrates and nitrites is darker than with diazobenzol but before positive conclusions are arrived at other tests must be made

[3] Annalen der Chemie und Pharmacie, B 137, S 54

although the cat could walk about the room, it was unable to retain any food Several times it was seen to lap a little milk, but on doing so it would immediately begin to retch and vomit This condition continuing, after three days the animal was placed under ether, and its abdominal organs examined We certainly expected to find marked inflammation of the stomach, but we really did find the stomach and small intestines filled with a frothy serous fluid, such as had formed the vomited matter, and the mucous membrane very white and soft There was not the slightest redness anywhere along the alimentary canal

Experiment 3 —Some tyrotoxicon obtained from milk which had been inoculated with poisonous cream and allowed to stand for 48 hours was administered to a large old cat It soon produced retching, but no vomiting or diarrhœa The amount of the poison administered in this case was small

Experiment 4 —Some tyrotoxicon from milk was given to a young, but full grown cat Within 15 minutes there was marked and evidently painful retching, and within half an hour vomiting accompanied by rapid breathing Later there were several stools, the first two of which contained fæcal matter, but the subsequent ones were rice-water like and wholly free from fæcal odor After two days some more of the poison was given, and the vomiting and diarrhœa again induced The animal was then anæsthetized, and examination of the stomach and intestine showed the mucous membrane blanched as in experiment 2

We have the records of a number of other experiments with tyrotoxicon on the lower animals, but as the symptoms induced in all were substantially the same, it is unnecessary to note them here We will now give the effects observed in the lower animals after the use of the prepared diazobenzol

Experiment 5 —Gave to a large old cat, 100 milligrams of diazobenzol butyrate Immediately the animal began to purge Then she lay upon the floor breathing rapidly and retching severely for two hours, when she died The retching was most violent, but vomiting seemed impossible Post mortem examination showed the lungs greatly congested, but the mucous membrane of the stomach and intestine was not reddened The stomach contained some food I suppose that the congestion of the lungs was due to the violent retching

Experiment 6 —To a young but full grown Maltese cat, I gave 100 milligrams of diazobenzol butyrate With most violent retching, but without either vomiting or stool, the animal died within 30 minutes after the administration of the poison The lungs were found acutely congested, and the stomach free from any redness The circular fibres of the small intestine were tightly contracted

Experiment 7 —Gave to a full grown cat 25 milligrams of diazobenzol butyrate Within 10 minutes vomiting and purging were induced The first stools contained fæcal matter, but the subsequent ones were like rice-water, and wholly free from fæcal odor After two days the cat was able to take food, then 10 milligrams more of the poison was given, with the reproduction of the vomiting and purging The animal then rapidly emaciated, and after a few days, it was anæsthetized and the mucous membrane of the stomach and intestine found blanched The lungs were not congested

Experiment 8 —10 milligrams of the poison produced diarrhœa and continued vomiting in a cat

Experiment 9 —75 milligrams produced vomiting and diarrhœa with congestion of the lungs in a dog

It seems unnecessary to detail any more of these experiments, as the identity of tyrotoxicon with diazobenzol is now established, not only by chemical analysis, but this proof is strengthened, if chemical analysis can be strengthened, by the action of the poison on the lower animals and by post mortem appearance

I think it highly probable that diazobenzol or some closely allied substance will be found in all those foods, which from putrefactive changes produce nausea, vomiting and diarrhœa In some oysters, which produced these symptoms, I have recently found tyrotoxicon

Milk or other fluid to be tested for this poison should be kept in well stoppered bottles, for if the fluid be exposed to the air, the tyrotoxicon may decompose in a few hours The filtrate from the milk or the filtered aqueous extract of cheese should be neutralized with sodium carbonate, then shaken with half its volume of pure ether Time should be given for the complete separation of the ether Purified tyrotoxicon is insoluble in ether, and it probably owes its solubility in ether at this stage to the presence of impurities After complete separation the ether should be removed with a pipette and allowed to evaporate spontaneously from an open dish The residue from the ether may be dissolved in distilled water and again extracted with ether, but repeated extractions with ether are to be avoided, for as the tyrotoxicon becomes purified, it becomes less soluble in ether To a drop of an aqueous solution of the ether residue apply the preliminary test with sulphuric and carbolic acids To the remainder of the aqueous solution of the ether residue add an equal volume of a saturated solution of caustic potash, and evaporate the mixture on the water-bath The double hydrate of potassium and diazobenzol will be formed if tyrotoxicon be present, and this may be recognized by its properties and reactions which have already been described

The above mentioned experiments upon the cats and dogs strengthen us in the belief that the development of this poison in milk is a frequent cause of cholera infantum and kindred affections When we remember that these diseases are most prevalent among the poor classes of our large cities, where fresh milk is almost unknown, we can readily understand their frequency By such people milk is often not obtained until it has begun to sour, then it is kept at a high temperature and often in a most foul atmosphere and we all know something of the readiness with which milk takes up bad odors This milk is then eaten by the little ones who are weakened by poverty and everything that poverty means, insufficient food generally, and that of the poorest

quality, insufficient clothing, insufficient and vitiated air With these facts before us it is not surprising that in all our large cities thousands of children die annually from the summer diarrhœas Moreover, in our country places, how little attention is given to the food of children, we all know from actual observation Cows stand and are milked in filthy barns and yards The udders are generally, so far as my observation goes, not washed before the milking, the vessels for the milk are frequently found not as clean as they should be Then there are the thousands of children that must draw their sustenence from bottles, the cleansing of which is in many families not properly attended to Crusts of decomposing milk form around the neck of the bottle, in the tube and nipple, lead to the rapid decomposition of the entire contents of the bottle I think that one of the most important advantages to be secured to breast-fed children arises from the lessened danger of infection of the milk with germ which may produce poisonous ptomaines

I would not claim that decomposed milk is the sole cause of the summer diarrhœas of children, nor would I claim that tyrotoxicon is the only poison that may be developed in milk It is *only one of a large class of bodies which are produced* by putrefaction, and many of these are cathartic in action

But will this knowledge concerning the development of poisons in milk and other foods aid us in the prevention and treatment of these diseases?

Preventive measures will consist for the most part in attention to the diet, and especially in milk I have drawn up the following rules concerning the care of milk

1 The cows should be healthy, and the milk of any animal which seems indisposed should not be mixed with that from the perfectly healthy animals

2 Cows must not be fed upon swill, or the refuse of breweries, or glucose factories, or any other fermented food

3 Cows must not be allowed to drink stagnant water, but must have free access to pure, fresh water

4 Cows must not be heated or worried before being milked

5 The pasture must be free from noxious weeds, and the barn and yard must be kept clean

6 The udders should be washed, if at all dirty, before the milking

7 The milk must be at once thoroughly cooled This is best done by placing the milk can in a tank of cold spring water or ice-water, the water being of the same depth as the milk in the can It would be well if the water in the tank could be kept flowing, indeed, this will be necessary unless ice-water is used The tank should be thoroughly cleaned every day to prevent bad odors The can should remain uncovered during the cooling, and the milk should be gently stirred The temperature should be reduced to 60° F within an hour The can should remain in the cold water until ready for delivery

8 In summer, when ready for delivery, the top should be placed on the can, and a cloth wet in cold water should be spread over the can, or refrigerator cans may be used At no season should the milk be frozen, but no buyer should receive milk which has a temperature higher than 65° F

9 After the milk has been received by the consumer, it should be kept in a perfectly clean place, free from dust, at a temperature not exceeding 60° F Milk should not be allowed to stand uncovered, even for a short time, in sleeping or living rooms In many of the better houses in the country and village, and occasionally in the cities, the drain from the refrigerator leads into a cesspool or kitchen drain This is highly dangerous, there should be no connection between the refrigerator and any receptacle of filth

10 The only vessels in which milk should be kept are tin, glass or porcelain After using the vessel it should be scalded, and then, if possible, exposed to the air

With the attention demanded by these rules given to milk, it will become more valuable as a food, and the development of poisons in it before its introduction into the body will certainly be prevented

But in the prevention of the summer diarrhœas, attention to the food must not stop with its introduction into the body The ferment which produces tyrotoxicon is widely distributed, and it only awaits conditions suitable for its development We do not know exactly what germ it is that produces this poison, but it is either the butyric acid ferment or some ferment which is frequently developed along with the bacillus butyricus, because I have found that if some butyric acid ferment be prepared according to the method usually followed in making butyric acid, and milk be inoculated with this and allowed to stand at the temperature of the body for a few hours, or at the ordinary temperature of the room for several days, the poison will appear Moreover, as is well known, the bacillus butyricus grows best in the absence of air, we have already seen that the exclusion of air favors the development of tyrotoxicon We are aware of the fact that the butyric acid ferment frequently does develop in the stomach Therefore, I think that the prevention of these diseases necessitates some attention to digestion If the food lies in the stomach or intestine undigested, putrefactive changes will occur there

During the hot months, children, which are allowed to take food at will, often drink large quantities of milk simply for the purpose of quenching thirst Especially is this true when the patient forgets that a child would sometimes relish a drink of good water I feel that this overloading the stomach with milk caused by thirst often is of no little detriment It is hardly necessary to specify in regard to other ways in which attention should be given to the digestive organs of children Those that partake of other foods with their milk should be allowed only the most wholesome articles, and these should be in perfect condition Moreover, the depressing effects of extreme heat on the nervous system and its consequent injury to digestion should always be borne in mind

Now, we come to the discussion of the curative treatment of these diseases The first thing to do is

to stop the administering of milk in any form The ferment is present in the alimentary canal, and giving the best of milk would simply be supplying the germ with material for the manufacture of the poison This no milk treatment is not by any means a new idea It has been taught for some years by a few of the best authorities, but it has not been sufficiently insisted upon Moreover, the reason for it has not been hitherto understood It was believed in somewhat of a vague way that the digestive organs lose their capability of digesting milk, and experience showed that the exclusion of milk led to improved results But now that we know that a powerful poison is formed from the putrefaction of the milk, the necessity of its exclusion must become apparent to all I reported last year a case which is so applicable here that I must be pardoned for quoting it in full If the child had been an animal upon which I wished to experiment I could hardly have selected conditions more favorable

"July 30, 1886, about 1 o'clock P M , I was called to see the seven months' old babe of Mr B I found that the child had been vomiting quite constantly for some three hours It had also passed watery stools some six or seven times The eyes were sunken, skin cold and clammy, and pulse rapid and small I diagnosticated cholera infantum During the preceding night the child had seemed as well as usual, and had taken nourishment freely from the mother's breast Early in the morning it had been given a bottle of cow's milk, and soon thereafter the nausea and vomiting began Later, as stated above, the child began to purge The mother, furnishing an insufficient supply of milk, it had been the habit to give the child cow's milk several times through the day I prohibited the further use of milk, both that from the mother and from the bottle, and substituted meat preparations and rice water as food I also prescribed pepsin, bismuth subnitrate, chalk mixture, and camphoreted tincture of opium

"The cow's milk which had been furnished the child was from an animal kept by one of the neighbors On the evening of the same day that the child was taken sick I obtained two quarts of the morning's milk of this animal The milk had the appearance of very rich cream, being of a yellow tint throughout This milk was allowed to stand through the night of the 30th in the ice-box of a refrigerator On the morning of the 31st I began the analysis After pouring the milk from the pitcher there remained in that vessel about two ounces of a fluid the color of port wine Microscopical examination of this fluid showed the presence of pus and blood corpuscles The blood was also detected by obtaining the characteristic bands of oxyhæmoglobine with the spectroscope The milk, which had already coagulated, was filtered The strongly acid filtrate was rendered feebly alkaline with potassium hydrate and then agitated with absolute ether After separation the ether was removed with a pipette and allowed to evaporate spontaneously This residue was dissolved in distilled water and again agitated with ether This ethereal solution left, after spontaneous combustion, a residue which had a slightly brownish tint I did not obtain the crystals of tyrotoxicon, doubtless owing to this trace of impurity, but the residue had the color and taste of tyrotoxicon This residue dissolved in some distilled water and given to a cat produced retching and vomiting

"That tyrotoxicon was present in the milk taken by the child shortly before the beginning of its illness there could now be no doubt It is true that the milk was abnormal in other respects also, inasmuch as it contained pus and blood

"After the withdrawal of all milk and the use of the medicinal agents mentioned above, the child began to improve, and by the afternoon of August 1 it seemed so well that it was allowed a bottle of cow's milk (from another animal), but soon after taking this milk it began to vomit and purge Milk was again withheld and the same medicinal treatment resorted to This attack was slight, and after it the child continued to improve until the night of August 4, when the grandmother, 'who knew more about raising babies than the doctor,' fed the child bountifully upon milk Again the vomiting and purging began, and it was more than a week before all symptoms of gastro intestinal irritation had disappeared About the 15th of August milk was again allowed, at first in small quantity, and this seeming to have no harmful effect, more liberal quantities were given The child has continued well since "

That my experience in this is not unique will be made evident by the following quotation from a recent paper by Dr L Emmet Holt, physician to the New York Infant Asylum, who writes as follows "In children under two years of age not fed at the breast, it is better to withhold milk entirely This has been a subject of careful investigation during the past summer at the New York Infant Asylum, and both the resident physicians and myself have had this proved to our satisfaction by a large number of cases Peptonized milk is very much less likely to disagree than either condensed milk or fresh cow's milk But in many, even this caused an aggravation in the intestinal symptoms, particularly in severe and protracted cases Again and again have I seen relapses brought on when milk was added to the diet in cases where the stool had been practically normal for two or three days "

The food used may consist of chicken and mutton broths, beef juice, and rice or barley water With this list, no difficulty will be experienced in giving the child sufficient nourishment In the medicinal treatment the first thing to do is to cleanse the alimentary tract as thoroughly as possible In the first stages of the disease there is no better agent for this purpose than castor oil But if there have already been several serous discharges, copious enemata of water will be more suitable These injections may contain either an astringent or a disinfectant, or both For the latter, Holt recommends benzoate or salicylate of sodium, and for the former, nitrate of silver or tannic acid

The next thing to be done is to arrest the growth of the germ This germ has been found so far to develop only in acid media Therefore, I think it wise to administer some antacid Probably there is

nothing better in this line than the old chalk mixture In the preparation of the chalk mixture, the druggist should be requested to use glycerine, as many druggists still use syrup in this preparation The presence of the sugar leads to rapid decomposition during hot weather It has been said that the use of the antacid is irrational, because the discharges are often alkaline Of course, the serous discharges are often alkaline, because they consist of blood serum, and will be alkaline unless they have remained in the intestine long enough to ferment, but the reaction of such discharges does not prove that the contents of the stomach and small intestines are alkaline

As to the use of germicides, doubtless much is yet to be learned No doubt the chief effect of subnitrate of bismuth in this disease has been due to its effect upon the germ Holt makes an excellent showing for the salicylate of sodium, but since he has been using this drug, he has followed the no-milk diet and doubtlessly his lessened mortality has been due to the exclusion of milk quite as much as to the salicylate He uses this drug in doses of from one to three grains every two hours

I am now making some experiments with the object of ascertaining the effect of certain germicides on the development of this poison The results, I will give in some future paper, but I may state here what my success has been in a few experiments with mercuric chloride The method of conducting the experiment was as follows Four-ounce bottles were filled with milk, milk and ferment, and milk and ferment with mercuric chloride, closed with glass stoppers and kept in an air-bath at the temperature of the body for six hours Then the milk was tested for tyrotoxicon with the following results

No 1 Bottle containing pure milk only Result, no poison

No 2 Bottle containing pure milk only Result, no poison

No 3 Bottle containing milk and ferment Result, the poison present

No 4 Bottle containing milk and ferment Result, the poison present

No 5 Bottle containing milk, ferment and a one-hundredth grain mercuric chloride Result, poison present

No 6 Bottle containing milk, ferment, and one fiftieth grain mercuric chloride Result, poison present

DISCUSSION

DR J M AILEN, of Liberty, Mo, said that there was no evidence of inflammation after the diarrhœa from tyrotoxicon This is rare, for inflammation generally exists Milk alone is not the cause of summer complaint in children In the country not only is good milk obtained but, moreover, most country children are nursed by the mother Reflex irritation should be borne in mind as a cause Very rapid changes are going on in the gastro-intestinal canal of the growing child and we have excitability *plus* reflex action There is first arrested digestion in the stomach The secretion of the stomach is first interfered with, followed by fermentation of the food, by hyperæmia, and a state of inflammation He directed his attention to controlling reflex irritation and to the food

DR VAUGHAN said I doubt that there is active congestion in severe cases of cholera infantum The mucous membrane is bleached and whitened Tyrotoxicon acts by increasing reflex excitability, and not so much by irritation

DIARRHŒA INFANTUM AND ALLIED DISORDERS

Read in Section on Diseases of Children, at the Thirty Eighth Annual Meeting of the American Medical Association

BY GEO WHEELER JONES, M D,
OF DANVILLE ILL

At the close of the last meeting of the Association, held in St Louis, I promised Dr Miller, the Chairman-elect of this Section, to write a short paper on this subject, which had been pressing itself upon my mind for several years, and with growing force since the discussion in the Academy of Medicine, of Paris, of Gautier's paper on the result of the very important—not to say startling—investigations of Selmi in 1877, including much original matter as presented by himself Continued researches in this direction have only confirmed the principles enunciated by earlier workers The discovery of tyrotoxicon by Prof Vaughan, with the increasing number of suggestive cases and reports, seemed to me to justify the contribution I proposed to offer to this Section Since commencing the preparation of this paper Dr Emmet Holt has given us a valuable article on the same subject published in the New York *Medical Journal* of the current year

It is now more than a quarter of a century since I sat at the feet of our professional Gamaliel and listened to his views upon the causes of summer disorders in children Ptomaines and leucomaines were the undiscovered quantities, but the environment necessary for their suitable abode, and the circumstances necessary for their full development will never be more clearly described than I have heard in words from the lips of Prof N S Davis, while the treatment instituted to control the diseases pointed—as we now see—unerringly toward the discoveries and advancements of the near future, although the conservatism of his own mode of thought may have prevented him from fully consenting to much that the modern enthusiast claims as undoubted fact and axiomatic principle Under the teachings referred to I had grown to a full realization of the importance of heat as a factor in the production of intestinal disorders, but in the care of a regiment during the war—in an active service from the Mississippi to the Atlantic seaboard I learned rapidly to know that heat was only *one* of the elements to be combatted The commands of which I had charge were rather exceptional in healthfulness and a recent review of the prescriptions and advice which it was my custom to give show that I was unconsciously aiming my medical guns at micro-organisms in the use of germicides rather than at the patient in the use of opiates and astringents I merely mention this as a suggestion, for the principles involved are the same be the children 30 days or 30 years old

Entering upon an active practice at the close of the war, I early became dissatisfied with the routine treatment of summer disorders in children, losing important cases during successive years and upon the promulgation of the germ theory of disease, I eagerly investigated the same, accepted it as a probably satisfactory solution of the difficulties in the way of greater triumphs in the saving of our babies' lives Treatment based upon such acceptance proved wonderfully successful, as recorded in a paper which I read before the Illinois State Medical Society several years since Every season and every new case has only confirmed me in the correctness of the position now taken by many of our best investigators until it might almost be laid aside with the remark "it goes without saying," but for the other fact that only the few have a full realization of these things, and settled truths are only rendered potent in a large way by persistent reiteration, and a presentation from standpoints as varied as are the characteristics of human observers

Whether putrescence has its origin in hydrolytic action with the necessary agitation to the elective affinities, or in the deoxydizing power of micro-organisms the result is the same—and in the light of recent investigations we must look to these results for much that is the cause of disordered vital actions in the various derangements of the intestinal canal Older men, imbued with the earlier teachings, especially those who grasped at chemical action as the solution of the problems of biological research will long hesitate to adopt the lines of thought which lean towards the former view, only the most painstaking exactitude and the most positive proof from the thoroughly informed bacteriologist will be convincing, and even then the verdict may be the Scotch one with a truce to theory while practice shall follow the lead of the other side For my own part I am fully impressed with the capability of the micro organic theory of certain diseases to satisfactorily account for more of their peculiarities than any other view that has thus far been advanced, and in a successful combat with the diseases considered in this paper, I believe there will be found no more efficient means than such as will develop from a thorough knowledge of all those conditions which make toward the possibilities of micro organic development And for this very reason the recent review of the whole subject as necessitated by the presentation of Gautier's views before the Académie de Médecine has been productive of the most positive advance as yet made toward a fuller and more satisfactory consideration of the subject of bacteriology in its relation to doctors and disease

All putrefaction—all fermentation—is an accompaniment, if not a consequence of cell action and cell formation, *i e*, of cell life, the various processes having each its respective form of cell and cell growth as the basis of its incubation and continuance Whether the newly discovered factors in disease—the ptomaine products—are a result of cell disintegration is a sharply defined field for future research, that it may be the latter and that the term cadaver alkaloids bears a doubly potent significance there are many reasons for believing The action of one of these alkaloids within the system is prompt, and unvarying, awaiting no slow process of incubation and maturity Tyrotoxicon produces in a few moments all the most virulent symptoms of cholera infantum or milk poisoning, while an alkaloid from the culture fluid of the comma bacillus gives origin at once to typical Asiatic cholera, so far as the morbid phenomena can determine

And just here I will throw out the suggestion as to whether inoculation with, or ingestion of high attenuations of some special alkaloid might not prove a valuable prophylactic in the management of some one or more of the dreadful diseases to which it bears an apparent causative relation, this suggestion of course being founded upon a consideration of the processes promulgated by Jenner and Pasteur, the half-acknowledged success of Ferran in Spain seeming to point towards such a possibility All waste products, as is well known, may be poisonous—probably are under certain conditions of heat, moisture and organic life The idea of life is inconsistent without its accompanying thought of waste, be that life the micro or the mammal, and in that waste, be it from the vital activities of bone, muscle, nerve, or the active vitality of micro organisms within the body, there exists destructive potentialities against which the skill of man was naught until the present generation The life history of many of the ferments is only superficially known and the results of their existence obscure and intangible, but with some we are becoming quite well acquainted, and our near approach, we trust, will rob them of many terrors to our race

A localized epidemic consisting of frightful morbid phenomena raises at once the question as to the domestic supplies, food, drink, air, clothing, by some one of which—closely questioned in turn—the sources of the trouble are revealed, may be corrected and the further spread of danger thus averted, no appeal to incantations, no guess work, no supineness, the foe is being sought for in his abiding place and destroyed

There are many changes, structural and nervous, in food poisonings which are not accounted for upon the simple germ theories but which may be fully explained by referring their causes to the action of the cadaveric alkaloids in part or *in extenso* Many of these products have the physical organization and the special physiological action of the various vegetable alkaloids as strychnine, narceine, conine, etc, and in their toxic action will develop structural tissue changes which it is important to consider in arranging for the proper application of suitable remedies In an extensive burn we have the fire to remove, the pain and shock to overcome, and the destroyed tissue to cleanse and restore—three distinct stages and modes of action, each calling for its special line of care A return to this thought will occur in its proper place, when we are considering the question of treatment

As ptomaines may be elaborated wherever organized ferments flourish, and as they represent the chief toxic principles of decomposing albumenoids, said decomposition resulting from the action of cell life, which action tends normally to constantly reproduce

itself so long as proper material is obtained, and thus continue the morbid processes once set in motion, and as many of the ptomaines in the waste of various diseases, producing by their continued formation a continuation of the morbid condition in which they are found, it really seems to me that their relationship to disease *must* be considered in all cases in which said disease is caused by or associated with micro-organic life

Without entering into an elaboration of this branch of my subject which you will find has been accomplished by several far more capable and better prepared investigators, I shall proceed to offer to you some practical points for the general worker in medicine I believe that the true solution of the difficulties in the way of the practical physician will be obtained by a union of the two theories which, when first presented in antagonism by M Gautier, seemed to be utterly irreconcilable Remembering the suggestions—as the existing knowledge was rapidly reviewed, that the alkaloid depends upon cell decomposition for its own possibility, and that no germ life can exist without death and decay—you have the key to the thought to which I desire to direct your minds

Under ordinary circumstances the digestive organs are capable of overcoming a certain amount of fermentative change which may have taken place in the food ingested, in fact many an adult stomach seems to prefer a tainted meat to one too fresh, but I believe this arises largely from force of habit and from the fact that in most if not all such cases we find the germ destroyed and further change prevented in that direction by the indulgence in copious potations of strong alcoholic liquids than which there are few better germicides The processes of digestion also tend to destroy germ life, except in those instances in which the cell has a special adaptation to intestinal abode The liver products are powerful anti-ferments in a normal condition, and one of the most favorable symptoms in the treatment of the troubles under consideration is a copious discharge of bile into the intestinal canal, giving an almost invariable relief to all serious indications While emptying an engorged liver may have the effect of relieving a local complication, I believe its greater influence is manifest in a disinfection of the gut and a consequent suppression of the causes of further infection

In children the tissues are less able to resist the attack of morbific agents and nature makes an effort at compensation by making their livers much larger in proportion than they are in adults and, as a rule, if a child's bowel can be promply emptied and then washed with bile it speedily recovers from an ordinary intestinal derangement In what are known as the offensive diarrhœas of children, there is always an absence of bile or the product is of a vitiated and deranged character When from any cause the digestive processes become abnormal and the various secretions associated therewith become changed, and their varied components lightly held together the introduction of an external cause of further disintegration produces changes often of a rapid and resistless type A few days and nights with the thermometer in the nineties gives an impulse to putrefactive processes wherever devitalized tissue, a cell and a trace of moisture are brought together, and that, as we all know, is everywhere wherever humanity may congregate The same atmospheric condition permits an exaltation of body temperature in the child through its lack of tonic influence upon the trophic centres and peripheral surfaces by which the tissues—superheated through the rapid building changes of child life—are strained to the utmost tension in the effort of resistance against the potencies tending to excessive disintegration, a tendency which makes the secondary results of micro-organic attacks so often disastrous

The train of symptoms once inaugurated you too well know to have them reviewed at this time The introduction of a microbe of fermentation or putrefaction into the intestinal canal under such favorable circumstances is only the first step—and these germs are everywhere as suggested before The instinct of a child to put everything into its mouth leads the way to infection from a hundred unsuspected sources, and only the most extreme watchfulness and cleanliness in everything can avert the threatened danger The child at the breast has dangers in general to fear, with the special liability of the mother to inaugurate changes in her milk from the influences of disease, overwork, menstruation and the various disturbing passions of mind and body, but its dangers are trifling compared with the child that is carelessly fed from the bottle, the slop jar, the table and the street

Prof Vaughan has said in his modest way "cholera infantum and summer diarrhœa *may* be due to the action of tyrotoxicon produced by fementation in milk foods " I believe that a large proportion of such cases are so caused—far more than has been heretofore realized, and that most of the remainder may be traced to other sources of micro-organic life The amount of traumatic or local inflammation from other causes in children are few indeed The first ingestion of the food poison is of course met by a prompt effort to expel the same by emesis and purging where the amount is at all great—and if the effort is successful a few doses of the bromides or other nervous sedative is the only remedy needed Going a little further—a retention of a few cells in the folds of the intestines establishes a breeding ground for a continuance of the trouble, while the action of the special alkaloid upon the epithelial tissues tends to produce disintegration therein, and in its turn adds fuel to the fires only half spent Where the quantity of poison ingested is large the structure involved is often so great as to produce the most extreme shock with inability to recover When it is small a slower course is pursued and a more general involvement is manifest—the case drifting into the ranges of sub acute and chronic forms

In the special management of these disorders, my own course will probably best illustrate my views If called to see a child in the first symptoms of the first stage, while active vomiting is still present, or if from any cause I suspect the stomach contains any material, I give a prompt emetic, and I have never found anything better than a few grains of ipecac in a strong solution of chloride of sodium—the former

I always have in my pocket, and the latter, a powerful antiseptic and germicide, is found in every pantry, promptly following this with whatever antiseptic remedy of a pleasant taste and harmless action I find most convenient, some aromatic and sedative powder or solution, and minute doses of mild chloride of mercury, perhaps, for a few doses, especially if the discharges are putty-like and offensive, to be accompanied and followed the second or third day, if the case is not promptly restored, by very small doses of the bichloride in solution The persistent application of the warm pack to the body—to the water of which mustard or other irritant may be added—will be found an excellent adjuvant

If a stimulant seems called for the aromatic spirits of ammonia will prove efficient, and good brandy or aromatized whiskey may be given, but never wines or other fermented liquors, until the stage of convalescence is fully established, and then no stimulant is called for During the active period of the disease all milk and forms of milk food are withheld, because of the fact that the poisons within the body, along with the subnormal status of digestion, promptly taints such foods and make them only an additional source of irritation I am in the habit of withholding for awhile almost all foods as such, and giving some one of the numerous forms of nutrient tonics in minute doses One of the best of these is Phillips' "Syrup of Wheat Phosphates" The disorder in early stages is one which will bear much starving, as the rest to the digestive organs is invaluable

I rely upon no special remedy or combination of remedies Nature—our very best guide when we get acquainted with her—has provided innumerable means for combating these dangers, and it seems to be our chief duty to select that formula, in a given case, which will prove the most efficient, and which is the most readily tolerated The bichloride I do not give at first, because of its tendency to nauseate, and it has seemed to me to be better adapted to the second stage, when the tissues were softened and inclined to break down in putrefactive changes, *i e*, it is better adapted to overcome and avert the consequences of ptomaine action, than as a direct germicide—for which latter purpose the sulpho carbolates and the aromatic antiseptics, with mild antacids, are more easily borne and equally efficient

The solution of hydrastis and bismuth is an elegant remedy from which I have obtained fine results, especially in combination with "listerine," which is a compound of several pleasant vegetable antiseptics with boraco benzoic acid Resorcin is bitter, naphthalin is vile, and the salicylates very unpleasant—at least such is my experience and observation

Anisic acid—an elegant article—iodine, tannic acid, the turpentines, ergot, hamamelis, arsenic, camphor, chloral, opium, belladonna, quinine, etc, etc, all have their uses and their places in various formulæ, to suit the convenience or fancy of the physician or the idiosyncrasy of the patient Anisic acid seems especially adapted to cases in which there is a great accumulation of gases in the intestines, and an irritable condition of the muscular coats

Tannic acid is particularly indicated in dysenteric types and those cases where there is a remarkably softened condition of mucous membrane with hæmorrhagic symptoms It surely has an action apart from its chemico mechanical functions, as we may infer from its remarkable potency in overcoming the toxic effect of digitalis poisoning, and from the almost absolute freedom from cholera infection of those who use it largely in their special pursuits Given as tannate of quinine we have a remedy in the cases under consideration of easy availability and positive power

Hamamelis is another valuable remedy of which we know too little in actual practice As a local means of relief when there is great tenderness and undue relaxation of the rectum, I have obtained excellent effects from an enema of a combination of tannin, concet ext witch hazel, ergot and morphine in starch water after each evacuation from the bowels

Ergotin is a reliable drug for steadying the nervous system, when we find the vaso-motor and ganglia are losing tone and weakening in duty

Opium should be used with the most extreme caution and watchfulness, only seeking when we do use it to obtain its sedative and tonic effects

As to the other remedies mentioned, their proper positions in the line of management will readily suggest themselves to the thoughtful physician

I would only urge, in conclusion, that whatever special remedies or particular formulæ may be adopted, give everything in the smallest doses practicable and frequently repeated A minute but tangible dose of a well selected remedy, prepared in pleasant form and given every few minutes until its power is manifest, in these disorders of children, will generally succeed where larger doses at longer intervals will prove unavailing The causes of this are easily understood by those who care to seek therefor The theory is sound for the practice which we recommend—a practice which we know to be successful

---

FOREIGN BODIES IN THE AIR PASSAGES

BY D LACOUNT, M D,

OF CHILTON, WISCONSIN

I report these cases of foreign bodies in the air passages for the reason that I believe there are many cases in which foreign substances have entered the air passage and produced death either within a few hours or after prolonged suffering, with destruction of one or both lungs accompanied by symptoms closely allied to tuberculosis of the lungs, without any suspicion on the part of the attending physician as to the true cause of the disease while the patient lives Where a foreign body is suspected the post-mortem examination is resorted to, and finding the foreign substance clears up the doubt Parents are often unaware of the fact that a child has drawn a foreign substance into the trachea, and the attending physician is left to wander in the dark as to the cause of the attack under consideration A careful examination of the chest should be instituted where a foreign body is suspected and if such substance be found it will modify the subsequent treatment, and

take a great load from the physician's mind The following case illustrates this

Case 1 —H S , æt 4 years, on August 3, 1876, while sitting upon the floor playing with some beans and having some in his mouth, became frightened by my presence (I having stepped in to visit another child having an attack of the measles) and in the act of crying, as is supposed, drew one of the beans into its trachea The child continued to cry for a short time and had a mild fit of coughing, but no dyspnœa I left the house not thinking there was anything the matter with the child, to be called back to see him in the course of one hour, finding him with a high fever I made an examination of the chest, at this time I did not suspect a foreign body in the trachea, and found the left bronchus plugged so that very little air was admitted It is very unusual for the foreign body to enter the left bronchus In a large majority of cases, the right bronchus is the favorite locality as is well known, owing to certain anatomical peculiarities In this case, however, the foreign body had entered the left bronchus, producing a severe attack of pneumonia of the left lung which lasted ten or twelve days, and then gradually or partially subsided, and assumed a chronic form The patient became emaciated, had a cough, spasmodic in character, without expectoration, (the patient being too young to expectorate) and in fact all the symptoms of pulmonary tuberculosis, which at the end of six months ended in death The patient at the time of his death was sitting upon the floor playing, and in the act of coughing became asphyxiated and died Twelve hours after death I made an autopsy, and found on removing the sternum and costal pleura, an intense congestion of the outer surface of the left lung, with an accumulation of pus in the chest cavity The costal pleura was intensely injected In the upper lobe of the lung an abscess had formed of large size, and bursting had discharged its contents into the cavity of the chest In making an incision through the center of the lung, there were discovered numerous small or diffused abscesses On laying open the bronchi, I found the bean at the bifurcation all intact, but somewhat softened and enlarged, lying transversely plugging up both bronchi, causing death immediately The original position of the bean was in the left bronchus, and in the act of strangling it was dislodged from its situation and lodged at the bifurcation

Not being positive as to their being a foreign body in the air passage, the treatment was to combat the pneumonia, although somewhat apprehensive as to the real cause Under the circumstances in which I was placed, having a case of measles in the same house, and this child was expected likewise to be afflicted, it threw me off my guard and led me to think it might be the onset of an attack of that disease Of course, the onset was too abrupt, but still it left my mind unsettled as to the cause of the disease The patient not being asphyxiated at the time of swallowing the bean, and no severe symptoms presenting themselves and the parents not knowing positively that a foreign body had entered the air passage, if the surgeon had diagnosticated the case and was quite certain as to there being a foreign body in the bronchi, it would have been impossible for him to gain the consent of the parents to an operation It has been my experience that people will not consent to an operation until it is too late for it to prove successful and the patient is lost

Case 2 —H. M , æt 3 years and 4 months, while playing in a garret with another child swallowed a bean On the return of the parents, at 1 o'clock P M , they found the child coughing violently, and on questioning him disclosed the above fact The parents not being very intelligent did not suspect any serious trouble until the patient's cough increased and was attended with considerable dyspnœa The child gradually grew worse until 11 o'clock A M of the next day, when he expired I was called, but did not arrive in time to see the patient alive One hour after death I made a post mortem examination and found a bean well packed in the right bronchus

Now in *Case 1*, the foreign body was found at the bifurcation, but it had evidently been in the left bronchus for it could not have remained for six months where it was found At the examination, it was clear that the bean had located itself well down in the left bronchus, and in the act of coughing, just before death, was dislodged, carried to the bifurcation and immediately caused suffocation The foreign body being the same substance in both cases it is singular that the symptoms were so different, one terminating in death after six months, the other in from eighteen to twenty hours I am led to believe by this that a foreign body entering the left bronchus does not cause death so soon as when it lodges in the right The right lung being somewhat larger than the left there is more breathing surface left for the patient, although it would seem that this difference in size would not be sufficient to prolong a patient's life for six months I remember having a patient thirty years ago, an adult, who had received a gun shot wound in the left lung, lower lobe Inflammation set in, terminating in abscess, and the whole lung broke down into pus, except a small portion along the middle line, filling the left thoracic cavity, in other words, empyema Paracentesis thoracis was performed and a great amount of pus was discharged, and continued to discharge up to the time of his death, which occurred two months later Twelve hours after death I made an autopsy, and found only a small portion of the lung remaining, about the size of a man's hand This patient must have lived at least four months without any use of his left lung He died six months after receiving the gun shot wound

Case 3 —M J , æt 4 years, on March 14, 1885, while having carpet tacks in her mouth, one was drawn into the windpipe causing a severe fit of cougning, but no great dyspnœa She informed her parents of what had happened, and was immediately brought to my office On examination of the chest I came to the conclusion that the foreign body was in the right bronchus from the feeble respiratory murmur and a peculiar bronchial wheezing located just under the articulation of the second costal cartilage with its rib Emetics had been administered before coming

to me, also slapping on the back had been tried, but to no purpose Seeing no immediate danger unless it was from an attack of pneumonia, I advised the parents to make no further attempt to procure the foreign body In all probability the foreign substance would soon be expelled by coughing

After leaving my office they accidentally met a medical student from the College of Physicians and Surgeons, of Chicago, who recommended them to proceed immediately to the College, where one of the surgeons in attendance would perform tracheotomy and remove the tack His advice was accepted, and on arriving at the College, the patient was examined by Professors St John and McWilliams They came to the same conclusion, that as long as the patient was not in any immediate danger, they would refrain from operating and take the chances that sometime the foreign body would be expelled by coughing About a week or ten days after the patient returned home she was attacked with measles which ran its course in the usual time The disease was accompanied with severe bronchial irritation, and in one of the paroxysms of coughing the foreign body was expelled just four weeks from the time it entered the trachea and the patient recovered perfect health

Case 4—F R, æt 7 years, in July, 1885, while having the upper half of a sixpenny nail in his mouth swallowed it, and it passed into the trachea He immediately began to cough His mother, however, did not believe that the nail had entered the windpipe One week after the accident I was called, and found the patient laboring under a severe attack of pneumonia of the right lung, which ran its course in ten days and an effort was made toward convalescence During the pneumonic attack there was slight cough which soon subsided, the patient, however, remaining quite weak and feeble Four weeks from the day the foreign body entered the trachea, he had a severe paroxysm of coughing which lasted one hour, during which the foreign body was thrown out The child began to improve immediately and was soon in perfect health

In this case I think the foreign body was in the right bronchus I could not tell positively, for the reason that the pneumonic symptoms masked all others In all these cases it was not positively known that foreign bodies had entered the air passage, therefore no operation was performed for the relief of the patients In my opinion the mortality would have been greater if they had been operated upon According to statistics, in 75 cases without operation 70, or 93 33 per cent recovered, and 5 or 6 66 per cent died Of 34 cases in which bronchotomy was practiced 26, or 76 47 per cent recovered and 8, or 23 53 per cent died, a death rate 16 87 per cent greater than in cases without operation

MEDICAL PROGRESS.

SALOL IN ACUTE ARTICULAR RHEUMATISM AND ACUTE FEBRILE DISEASES —Salol was discovered by Professor von Nencki in Berne some years ago, but has hitherto been little used as a medicine Sahli, of Berne, has recently recommended it strongly for the treatment particularly of acute articular rheumatism and acute infectious diseases HERRLICH, after thoroughly testing it, is convinced of its value In salol there is an ether combination of 60 per cent of salicylic acid and 40 per cent carbolic acid It is salicylic phenol ether It is a white crystalline powder with an agreeable, slightly aromatic odor Its taste is bitter Salol bears a resemblance to fats as regards both its chemical composition and its physical properties Like fat, it cannot be dissolved in water, but is easily soluble in alcohol, ether, and in volatile and fat oils It possesses pronounced antiseptic qualities, equal, according to Nencki and Sieber, to those of salicylic acid It prevents the development of putrefactive germs, and meat can be kept by it for an unlimited time But it does not act to any considerable extent as a disinfectant, like sublimate Applied outwardly as a powder it is a powerful antiseptic, and being insoluble, it does not irritate the skin, as its component parts salicylic acid and carbolic acid do One drawback is that, owing to its pliant nature, it is difficult to bring it into the form of a powder Sahli recommends the use of sugar of milk in its pulverization Taken internally it is resolved, according to Nencki, into salicylic acid and carbolic acid by the action of the pancreas ferment Thus salol passes through the stomach unchanged, without particularly inconveniencing it, and only in the upper part of the small intestine, when it comes in contact with the pancreas ferment, does it fall into its component parts The mucous membrane of the small intestine absorbs the two acids so quickly that, soon after 2 grams of salol have been given, the two acids are traceable in the urine as salicyluric acid or phenol ether sulphuric acid The urine becomes of a greenish black or deep black color It is remarkable that while this symptom would, in connection with the surgical application of carbolic acid, indicate poisoning, it has no significance after the internal application of salol The dose recommended by Sahli is from 6 to 8 grams a day

The interest of the internal application of salol is chiefly connected with its carbolic factor What has been impossible is now feasible, viz to introduce with ease and safety large doses of carbolic acid into the body

Sahli has published a report in which he states that with salol acute articular rheumatism has been treated with the most favorable results, that its effect on endocarditic complications has been very good, and that it alleviates the pain of chronic articular rheumatism The only bad secondary effect mentioned by Sahli is tinnitus aurium Salol can be given only in form of a powder, the single dose being up to about 2 grams The powder is given in a wafer, or perhaps more easily in compressed tablets Herrlich treated more than thirty cases of acute articular rheumatism with salol, and in addition a number of chronic cases and some typical cases of muscular rheumatism, lumbago, and omalgia Acute articular rheumatism is very

favorably affected by salol and cured The effect on chronic articular rheumatism and muscular rheumatism is palliative Herrlich cannot determine how much of the anti rheumatic effect is due to the carbolic acid In the treatment of articular rheumatism, salol agrees with the patients if their general health is good, and has few bad secondary effects but it cannot prevent relapse, nor has it any apparent favorable effect on endocarditic complications Among his cases was one of a girl, 9 years of age, with acute severe feverish articular rheumatism He gave daily from 3 to 4 grams of salol in single doses of 0 5 grams The articular symptoms disappeared as if by magic But already in the first few days, as is so frequently the case with children, endocarditic complications appeared which in three months led to complete mitral insufficiency In a week there was the first recurrence of articular symptoms, which yielded promptly to salol The came another relapse which, by way of comparison, he treated with antipyrin, which did not prevent a further relapse The case was still under treatment

Herrlich has found that feverish articular rheumatism is particularly favorably influenced by salol This seems to agree with the action of anti-rheumatic remedies generally Herrlich treated with salol eight cases of typhoid, some cases of puerperal fever of the protracted pyæmic form, three cases of genuine pneumonia, two cases of ulcerative endocarditis, and one fatal case of diphtheria The stronger the general condition of the patient, the better was the effect of the salol Its antipyretic effect is fairly certain, and apyrexy is on the whole free from inconveniences, perspiration being also moderate No collapse of temperature was observed Herrlich found the disturbances of the stomach to be the most serious drawback in the use of salol in the case of weak typhoid patients, there being præcordial oppression, distension, and nausea, and in some cases vomiting and loss of appetite But in most cases the medicine agreed well with the patient There was one case of real carbolic acid poisoning in a woman suffering from chronic articular rheumatism, who had taken 24 grams of salol in three days—on the third day 10 grams She had violent vomiting, long continued loss of appetite, and general depression, from which, however, she recovered in a few days There was also a high degree of dysuria and tension of the bladder, with profuse urine containing much phenol

Shivering, which follows modern antipyretics, is sometimes observed after salol One typhoid patient suffered from it nearly always when the effect of the salol was ceasing, the temperature rising rapidly But this does not occur much more frequently than in the antipyrin treatment —*The London Medical Record*, July 15, 1887

VILLOUS PAPILLOMA OF THE BLADDER REMOVED BY SUPRAPUBIC CYSTOTOMY —E D PAOLI reports the second case of this kind in Italy The first, operated on by Marcacci, died Paoli's case was that of a woman, æt 47, who had had symptoms for 7 years The tumor could be felt through the dilated urethra, but was inacessible by the spoon, being at the vertex vesicæ Suprapubic cystotomy was performed, and the tumor easily reached The bleeding insertion was tamponed with liquor ferri temporarily, after hæmorrhage was arrested the bladder and skin were sutured in the upper two thirds, and a drainage tube and iodoform gauze placed in the lower third On account of insufficient distension of the bladder the peritoneum reached to the symphysis, and had to be pushed back Permanent catheter Transient fever on 16th day, with some fetid urine The patient recovered in a little more than one month The tumor was a simple papilloma —*Centralbl fur Chirurgie*, No 20, 1887

TRANSPLANTATION OF TENDON —PEYROT reports the case of a 14-year old boy who had had both flexor tendons of the middle finger cut, and after that the finger could only be flexed slightly with half of the interosseous The ends of the divided tendons were about 4 cm apart Peyrot united them with small pieces of tendon taken from a young dog at the time, and fixed the pieces with catgut While the wound in the skin did not heal by primary union, the pieces of transplanted tendon healed in On account of adhesions with the cutaneous cicatrix movement was not complete, but was very much better than before the operation —*Centralbl fur Chirurgie*, No 20, 1887

DIAGNOSIS OF BEGINNING CARCINOMA OF THE CERVIX —Since experience has shown that beginning carcinoma of the cervix can be entirely cured by operation, it is important that family physicians send the patients to the specialist early And in order to make at least a probable diagnosis without microscopic examination of an excised piece, C H STRATZ says that from his observation and that of others the important signs of carcinoma are as follows

1 The diseased place is sharply limited by sound tissue, and never goes over into it by degrees

2 A difference in the level of the whole diseased portion can always be made out

3 Carcinomatous portions have always a light yellow color

4 The malignant deposit is usually shown as finely granular, whitish yellow glistening elevations, at least in individual places —*Centralbl fur Chirurgie*, No 25, 1887

TREATMENT OF SCABIES —FOURNIER advises

1 A thorough soaping of the parts, followed by a full bath

2 Frictions over the body with the following mixture

℞	Glycerine	2 parts
	Gum tragacanth	1 100 part
	Flowers of sulphur	1 "
	Carbonate of soda	½ "

After this a second full bath must be taken The linen of the patient and the bed linen must be carefully laundered, and gloves which have been used must be burned On the next day it will be useful to give emollient baths, and to apply powdered starch or glycerite of starch —*Nouveaux Remedes*, May 24

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE INCLUDING POSTAGE

PER ANNUM, IN ADVANCE	$5 00
SINGLE COPIES	10 CENTS

Subscriptions may begin at any time The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible remittances may be made at the risk of the publishers by forwarding in REGISTERED letters

THE CONGRESS IN WASHINGTON

In more than one respect was the Ninth International Congress a success Some of our visiting confrères from Europe say that from a scientific standpoint no Congress ranks higher, and that the proceedings, when published, will reveal a wealth of learning among Americans of which the profession generally in Europe has been entirely ignorant It is not from a boastful spirit that we quote this opinion, though even in that case we might be pardoned, since, truth to tell, many things have been said of us on the other side of the ocean that were anything but flattering

Heretofore the knowledge of Europeans and Americans of one another—or we may in this case speak generically and say, of each other—has been one-sided This is to be explained in great part by the one sidedness of the visits Many Americans go to Europe, but comparatively few Europeans come to America Many of the Americans who go abroad, while wealthy, are not of the kind to produce a pleasant impression or raise our country and institutions in the estimation of foreigners

Let us hope that whatever pleasant impressions were produced on our visitors from abroad, from whatever country they came, may be so lasting that they and others may be induced to visit us again, and that too before another International Medical Congress meets in this country We would gladly know them better, and would have them know us better We would have them feel, and will endeavor to show them that as science is not bounded by geographical lines nor limited by oceans or mountain chains, and as each laborer in the field of science, however humble and unknown he may be, can claim all other workers as his brothers, more especially when their chosen field of labor is the alleviation of human suffering, so hospitality, good feeling, brotherly kindness can and do have a home in America It is not impossible that many of our visitors came, as Dr Martin of Berlin said he came, with some doubts Let us hope that, like him, all went away from Washington with the doubts all removed And such was the case if he, and Dr Grailey Hewitt, Dr Landolt and Dr Edmund Owen represented in their remarks on the last day of the Congress the sentiments of the other visitors Dr Hewitt said he was requested on the part of the foreign members of the Congress to express in a few words the sense which was entertained by them of this Congress and of the efforts which had been made by the Executive Committee of this Congress for the furtherance of the objects of this great meeting, and to convey to them the grateful thanks of the foreign members for the attention bestowed upon the matter and their grateful appreciation which has attended their efforts He desired also to express their sense of the hospitality and the kindness and attention which they had received, both in public and in private, which would make their visit to Washington a source of gratification and happy memories in the future

Dr A Martin, of Berlin, expressed in German his thanks for the kindness he and other members of the Congress had received and gratification at the success of the Congress He had come here with some doubts These were all removed, and the great success of this Congress would secure it a high rank among the Congresses that have been held It had been the custom to engrave the names of the victors at Olympic games on plates of gold They could not so record the names of their entertainers, and the only means of expression for their sentiments was by a vote of thanks

Dr Landoldt, of Paris, said "I have been commissioned to express to the President of the United States our sentiments of profound gratitude Although feeling that I am unable to find words proper for the occasion, I accepted the honor, since the gratitude that springs from the heart has no need of eloquence to make it understood " When the applause that this sentiment produced had subsided Dr Landolt proceeded, saying

"Mr President and gentlemen, we have already assisted at a series of International Congresses We have been well received everywhere The countries of Europe have rivaled each other in their zeal to make our stay with them in their most beautiful cities pleasant, but it has not often been our lot to see the Chief of the State mingle in person among us and take part in our la-

bors The President of this great Republic came among us to bid us welcome with his sympathetic voice He invited us to his own home and gave to each of us a hearty grasp of the hand, significant of his most cordial hospitality The sanction given by President Cleveland to our Congress has given the greatest charm to our stay in this Capital Returning to our hearths we will preserve the most grateful and respectful remembrance of the President of the Republic, and we say to the whole world that the United States, already so favored, possesses above everything a Chief who directs them surely in the way of progress and prosperity "

Dr Edmund Owen thought he was admirably qualified to discourse on American politics, as he was entirely ignorant of the subject In science we have no politics "We are extremely happy," he said, "to have visited the United States during the Presidency of Mr. Cleveland" He said he asked an American friend the other day, and a very intelligent man, if he voted for Mr Cleveland, and the American said "no" Then he asked the American if he were satisfied now, and the laconic answer was, "guess I am" "If that question were put to this meeting, 'are we satisfied?' I say 'guess we are' A great man like the President might have found something else to occupy his attention, say, in the White Mountains about this time of the year, he might have been driven away by the doctors, but instead of that he remained here to welcome them When the history of this grand country is written we trust President Cleveland will have a niche in the temple of fame side by side with those great men, Lincoln and Garfield When you are in our country we love to hear you say, 'We admire your Queen' We can say to you with all truth, we admire, we love your Queen, her beauty and grace, and in seconding this vote of thanks, we simply express a prayer that Mr President Cleveland and Mrs Cleveland may long continue in strength and health to preside over a happy, a prosperous, and a united country "

We are sure that few if any will regret that the next Congress will be held in Berlin, and more especially since it will be presided over by the greatest of the great medical men of a great nation Medicine is indebted to Germany for much, but probably most of all for Rudolph Virchow

---

THE NEW LOCAL ANÆSTHETIC

A few months ago we noticed the discovery by an Australian physician of an alleged new local anæsthetic, drumine, which does not thus far seem to have fulfilled all that was said and expected of it It is to be hoped that the latest addition to our meagre list of vegetable local anæsthetics will not prove to be also a disappointment

Stenocarpine, a supposed alkaloid from the leaves of a botanically unknown tree, after being tested by Dr A M Seward, of Bergen Point, N J, and Dr J Herbert Claiborne, Jr, of New York, has been more recently examined and carefully tested by DR EDWARD JACKSON, of Philadelphia, who reports his observations in the *Medical News*, of September 3, 1887

Before further describing its action it should be said that, whether the name "stenocarpine" will finally prove to be the correct term or not, it should not have been given to the drug until the tree from which it is obtained is definitely and botanically determined As the matter now stands it is not at all certain whether the tree is the *Acacia stenocarpa*, *Gleditschia tricanthos* (Honey Locust), or *G meno-sperma* (Water Locust), though the leaves are said to resemble those of an acacia Mr Goodman, a veterinary surgeon, who first noticed the apparent anæsthetic properties of a poultice made from "a pile of leaves raked hap-hazard from the ground," says that the source of the leaves containing the anæsthetic principle is known in Louisiana, where the substance was first used, as the Tear-blanket tree, which bears pod 8 or 10 inches long and slightly curved, containing seeds and a viscid juice The tree grows to a height of 35 or 40 feet, with a diameter to the bole of about 18 inches, and a spread of foliage of about 30 to 35 feet The tree is furnished with clumps of forked spines or thorns, long, tough and highly polished This description corresponds very closely, if not exactly to what is known in the Southern States—and as far North certainly as Virginia—as the Honey Locust

Dr Seward found that it produced local anæsthesia in the eye of a cat, and Dr Claiborne found that it produced local anæsthesia in the eye of the rabbit and of man, that gtt ij of an aqueous solution produced complete insensibility of the cornea and conjunctiva in a few minutes, with dilatation of the pupils, the anæsthesia lasting about half an hour, and the dilatation of the pupils for 36 hours As Dr Claiborne reported that in some cases a few drops of a 2 per cent solution on the skin caused almost absolute anæsthesia, so that tumors, warts, *etc*, could be painlessly removed Complete local anæsthesia was also produced in the nose, and the instillation of a few drops in the ear permitted the touching of the membrana without pain

Dr Knapp, of New York, also experimented with the substance and produced anæsthesia of the mu-

cous membranes of the eye, nose, throat, urethra and rectum Given hypodermatically it produced local anæsthesia of the skin, and a drop on the glans penis produced anæsthesia Injected into the cellular tissue of rabbits it caused violent attacks of tetanoid convulsions, of which opisthotonos was a prominent feature, recurring every 10 to 40 seconds for about 15 minutes, and followed by recovery in an hour From ♏ 5 to 25 was required to produce these symptoms Death in 10 seconds was caused in a rabbit by the injection of ♏ 10 into a vein of the ear, fibullary convulsions or tremors of the anterior portion of the body preceding death The symptoms closely resembled those caused by strychnia poisoning

Dr Edward Jackson experimented with some of the 2 per cent solution It was clear, of a faint brown tint, and distinctly bitter, and a few seconds after its application to the tongue and lips there was a peculiar sensation of the numbness precisely similar to that caused by cocaine, but more intense than that caused by the 4 per cent solution of cocaine Dr Jackson has not seen constitutional symptoms produced in any human subject, though this may be accounted for by the fact that not over ♏ iv of the solution were used in any one case He placed gtt j in his left conjunctival sac, causing smarting more severe than any similar application of a 4 per cent solution of cocaine, but still not severe, and passing off in a few seconds This was followed by a feeling of "stiffness," "dryness," or "coldness" of the lids, such as cocaine produces, and an immediate widening of the palpebral fissure Within 2½ minutes there was complete anæsthesia of the conjunctiva and cornea In 20 minutes the anæsthesia was less complete, and in 1 hour entirely gone The power of accommodation was very nearly or quite abolished in some cases by a single instillation, and was always abolished if the instillation was repeated When no other mydriatic was used recovery of the accommodation and pupil was almost complete at the end of 3 days When the drug was used to paralyze the accommodation in order to determine the refraction the results were satisfactory, in one case the subsequent use of duboisine revealing no additional hyperopia When used simultaneously with duboisine, homatropine or hyoscyamine it caused a wider dilatation of the pupil than did the other mydriatic

Dr Jackson could not determine positively that it caused any change in the degree of intra-ocular tension In no case could it be perceived that the corneal changes which are sometimes produced by a 4 per cent of cocaine took place after the use of this new drug There seems to be less blanching of the conjunctiva in the normal eye and in those eyes suffering from acute catarrhal conjunctivitis than is the case from the use of a 4 per cent solution of cocaine

When injected under the skin of the forearm gr jss of the solution caused complete anæsthesia of an area about 4×8 mm in extent, reaching mainly from the seat of the injection *towards the extremity of the limb* The anæsthesia was noted instantly, but seemed to extend its area for about 10 minutes, and disappeared in half an hour By applying it externally to the skin Dr Knapp failed to produce anæsthesia, but Dr Jackson produced complete anæsthesia in this way The point of application was simply kept moist with the solution, and the anæsthesia was very marked in 10 minutes, and continued to increase for 30 minutes, at the end of which time a needle could be plunged into the skin without the slightest sensation In one of these trials on the flexor surface of his forearm, at the end of 10 minutes Dr Jackson began an incision, and keeping the blood wiped away and the surface continually moist with the solution, completed it within 5 minutes more, to the depth of 3 mm , without the slightest unpleasant sensation, either at the time or afterwards The anæsthesia is very superficial, and to make a painless incision in the skin it must be done by repeated superficial cuts with the knife, and at the same time keeping the cut surface bathed with the solution A very important point, according to Dr Jackson, is that the skin must not be previously treated with soap and water, or with any alkali, as in this way the alkaloid of the solution is promptly precipitated—and this is most probably the cause of Dr Knapp's failure to produce anæsthesia of the skin by direct application of the solution But when the alkaloid has been thus precipitated on the skin the application of a dilute acid solution will bring about anæsthesia

In Dr Jackson's opinion the solution used, said to be a 2 per cent solution, is a more powerful anæsthetic than the 4 per cent solution of cocaine, though the new drug seems to exert less influence on the local circulation and nutrition of the cornea than cocaine It has a much greater power of paralyzing the accommodation than cocaine And yet "the recovery after the use of the new drug is more rapid than after any other efficient mydriatic, except homatropine, and it has a more powerful influence over accommodation than homatropine The superiority of the new drug in this direction is especially manifest in its ability to overcome the influence of eser-

me Thus the influence of cocaine on the pupil is overcome by one-fiftieth of its weight of eserine, and its influence on accommodation by still less Homatropine is neutralized by one eighth its weight of eserine But this drug requires two thirds or four-fifths of its weight of the myotic to overcome it If it is a local anæsthetic more powerful than cocaine, and a mydriatic more powerful yet brief in its action as homatropine, it must be a new drug, and one of great practical importance "

NEW DISEASE OF THE LIPS AND MOUTH

MR JONATHAN HUTCHINSON has recently drawn attention to a disease which, he believes, up to the present has not been recognized It is a form of inflammation of the lips and mouth in which superficial ulcerations occur, followed sooner or later by some form of skin disease and leading to a fatal termination The exact form of skin disease varies, but the hands and feet are the parts usually affected, the nails being especially prone to suffer In some cases the eruption may consist of bullæ, followed by free papillary outgrowths No special antecedents can be alleged as the probable cause of the malady, but the disease has only been observed in middle life or in early senile periods If not checked by treatment the disease appeared to run its course in about six months, death being produced by exhaustion Mr Hutchinson considers that opium given in repeated doses will cure it, and that there is hardly any tendency to relapse afterwards All the best marked cases he had observed in males, but in several milder ones the patients were women Careful inquiry had failed to support the suspicion that the disease might be due to contagion from animals He has lost two patients by death, both were those first observed, and since the discovery of the signal efficacy of opium, no case had ended fatally The observation as to the efficacy of opium was simultaneously made by Mr Pollock and Mr Hutchinson, two different patients being at the same time under their separate treatment and recovering under this drug Since that, every case yielded if the dose of opium were sufficiently pushed In one, however, the disease did not yield quickly, and for more than a month seemed likely to end in death As regards permanency of cure, in one case the patient was known to be quite well four years after his recovery, in another the same result had occurred, and in a third a period of two years had elapsed In two of the milder cases, the disease had repeatedly recurred A great variety of remedies was tried without benefit before the use of opium was resorted to One thing particularly noted was the fact that in no single case had there appeared to be any tendency to spontaneous improvement In all cases the inflammation of the mouth and lips took precedence of the skin symptoms, and in some the latter were very slight Another fact was that he did not know of any case that had as yet been obtained amongst the poorer classes of society Mr Hutchinson suggests that the affection is allied to other forms of disturbed health attended by skin disease and occurring in early senile periods, such as certain peculiar varieties of pemphigus, pityriasis rubra, psoriasis and lichen planus In confirmation of this suggestion he mentions a case of an elderly lady who had a kind of spreading eczema-psoriasis of the hands and scalp She lost her hair and nails, and was rapidly failing in health in spite of various measures of treatment, but finally recovered quickly and completely under opium, but her case did not belong to the class described, because she never at any time had inflammation of the mouth

A MYOPIC HORSE —One of the attractions, and an observed of all observers, of the Clinton market-place in Boston not long since, as we learn from a daily paper, was a horse wearing spectacles The animal was very near-sighted, and an oculist took the necessary measurements and had a pair of concave glasses made for it Unfortunately the report does not state just how the animal was examined, whether he can count fingers at ten feet, or what Jaeger test type he can now read

SOCIETY PROCEEDINGS.

AMERICAN DERMATOLOGICAL ASSOCIATION

Eleventh Annual Meeting, held in the Hall of the State Medical and Chirurgical Society, Baltimore, August 31 and September 1 and 2, 1887

(*Concluded from page 347*)

THURSDAY,—SECOND DAY

At the business meeting the following were elected

OFFICERS FOR THE ENSUING YEAR

President —Dr I E Atkinson, of Baltimore
Vice-President —Dr P A Morrow, of New York
Secretary and Treasurer —Dr G H Tilden, of Boston

The report of the Committee on the *Congress of American Physicians and Surgeons* was received and adopted

Dr I E Atkinson, of Baltimore, was appointed

representative to the Executive Committee of the Congress, and Dr G H Tilden, of Boston, alternate

Dr E B Bronson, of New York, presented a

CLASSIFICATION OF DISEASES OF THE SKIN

The classification was made upon an anatomical basis The cutaneous affections were divided into the following five classes 1 Idiopathic neuroses 2 Angioses 3 Epidermidoses 4 Cryptoses 5 Dermoses Diseases of the skin were further subdivided into sub orders, tribe, families, genera and species

Dr P G Unna We can never have a complete, definite, scientific classification of affections of the skin. As the knowledge of disease progresses so must our classification change The ideal classification would be one made not upon an anatomical but upon an etiological basis

Dr L D Bulkley I would express great admiration for the classification which has been presented, but I think that it is hardly suited for practical every day use As an attempt to scientifically classify diseases of the skin, it is far in advance of any classification yet offered

Dr L A Duhring, of Philadelphia, read a paper on

THE DIAGNOSIS OF DERMATITIS HERPETIFORMIS

The author had been led to believe from the perusal of various reports of cases that this affection was not thoroughly understood He therefore thought it desirable to offer some remarks with reference to its diagnosis The chief characteristic of the affection is the multiformity of the lesions manifested in the natural evolution of the disease If a given case remain sufficiently long under observation, multiformity of lesion will sooner or later be noted, and this will repeat itself Blebs, vesicles and pustules may appear together or separately Mixed eruptions are the most common, vesicles predominating In one attack or another only one kind of lesion may be present The disease presents clearly defined characters in distinct elementary lesion, and certain distinctive abortive lesions Secondary forms of lesions also exist Pigmentation of a dirty yellow or brownish hue, and variegated, is usually a marked feature in chronic cases Excoriations from scratching, with thickening of the skin, usually exist In no other affection are such varied combinations of lesions met with as in dermatitis herpetiformis Erythema and vesicles, or vesicles and blebs, or blebs and pustules frequently exist side by side in close proximity with more or less pigmentation, excoriation and secondary changes Itching is usually a most distressing symptom, and is most severe in the vesicular variety In the pustular form, subjective symptoms may be wanting The disease is extremely chronic, extending over a number of years In two cases under the author's observation, the duration had been thirteen and eleven years respectively, and the disease was still active, with no prospect of cure The eruption tends to recur at variable periods, usually six or eight weeks Some cases of dermatitis herpetiformis closely resemble cases of erythema multiformis, but the lesions of the former disease are less sharply defined and the course of the two affections is different, erythema multiformis, being an acute disease of short duration The disease occasionally resembles herpes iris, but the chronicity of the affection would exclude herpes iris The lesions are also more virulent and accompanied by a more profound degree of cutaneous disturbance Herpes iris is a benign affection, running an acute course and terminating in recovery, although subject to relapses When the bullous varieties exist alone they may resemble pemphigus vulgaris The combination with other lesions will, however, prevent any confusion in the diagnosis

With reference to the term dermatitis herpetiformis, the author stated that he had adopted it in preference to dermatitis multiformis for the reason that there was already a disease named erythema multiformis, and the use of the term dermatitis multiformis might lead to confusion and give rise to the opinion that it was simply an advanced stage of erythema multiformis

Dr L D Bulkley I wish to briefly report a case showing some of the difficulties of diagnosis A man was admitted to the hospital with remarkable skin lesions, and the case was regarded by all who saw it as one of dermatitis herpetiformis The patient was suffering with fever, and the temperature remained high until death In connection with the lesion of the skin there was a general alopecia of the body At the autopsy, generalized sarcoma was found affecting the spinal cord and various internal organs Whether or not the cutaneous lesions were simply the manifestation of the internal disease I cannot say

The President I cannot help thinking that the author has included in his description diseases of quite different nature Some of these cases are analogous to the old hydroa, others may be of septicæmic origin, while possibly some may be the result of local irritation It seems unphilosophical to consider these different conditions under one head I have seen as the result of bites of insects, lesions corresponding to those described in some of the cases of dermatitis herpetiformis I should hardly consider such a case as an example of this disease

Dr P G Unna, of Hamburg read a paper on

THE TREATMENT OF LEPROSY

The speaker, after referring to the fact that leprosy was usually considered incurable, and that as a consequence treatment was not resorted to, stated that he had recently treated five cases of this affection with encouraging results The treatment consists in the external use of the following ointment

Chrysarobin	5 parts
Ichthyol	5 "
Salicylic acid	2 "
Vaseline	100 "

This is applied to the nodules on all parts of the body, with the exception of those on the face, neck and hands In the latter situations pyrogallic acid is substituted for the chrysarobin in the above formula Such an application may be continued for months For some of the older nodules this is not sufficiently strong, for these the author uses salicylic acid or salicylic acid and chrysarobin in the form of

erator, and a born teacher He is only 47 years old, but looks much older He is of slender build, and his whole appearance suggests thoughtfulness and hard work

The surgical wards under his charge contain only 60 beds, but many rare and interesting cases His large operating room is intended only for small operations before the whole class, and for demonstrations and examinations of cases from the Policlinic In this room advanced students are allowed to perform minor operations under his personal supervision The more important operations are performed in a smaller room, which is supplied with every possible convenience for antiseptic work, it is the most perfect operating room I have seen, Volkmann's not excepted To the operations performed in this room only 5 or 6 students are admitted, and the regulations in writing posted on the door require that the students must not have been recently in the dissecting room or the pathological laboratory, and that they must come without collar, necktie, coat and vest, in fact must come into the operating room with nothing but shirt and breeches In how far the female students who attend Kocher's clinic can and will comply with these rules I am unable to say, as none of them came during the days I attended

For irrigation corrosive sublimate solution is used, for general use only 1 5000 When stronger solutions were used intoxication occurred quite frequently The wounds are covered with a flannel compress of sublimated gauze, generally dusted over with iodoform just before it is applied, and over this a cushion of aseptic moss

Kocher has a way of suturing wounds which should be more generally known, as it is done rapidly and neatly It is a form of continued suture, either with fine silk or catgut A long straight needle is threaded with the suturing material, and as an assistant makes traction with a blunt hook upon each angle of the wound so as to straighten its margins (a procedure which greatly facilitates the suturing) the needle is passed alternately deeply and superficially, so that approximation and coaptation sutures follow one another In this way a large wound can be stitched accurately in a few minutes For drainage, glass tubes or rubber drains are used Kocher's hæmostatic forceps are the best for general use His struma director is not only a useful instrument for strumectomy, but is very handy in all operations in which deep dissections are necessary close to large vessels

As I was passing through the surgical wards I counted 4 patients who had been recently operated on for struma, and they were all doing well Kocher informed me that recently wounds were inclined to suppurate a little, and he was unable to trace this to any tangible cause, but was inclined to believe that the catgut which was used was not quite aseptic He has been using catgut prepared in the ordinary way, but will return to his juniper catgut Dr Cavel has examined catgut made by Kocher's method, and has not always found it aseptic By experiment he has found that if the raw catgut be immersed in oil of juniper for 10 days it is perfectly aseptic, and if afterwards kept in absolute alcohol it remains so permanently He advises that when the catgut is taken out of the juniper oil it be washed with sulphuric ether before being transferred to the alcohol, as otherwise particles of oil cling to it and irritate the wound

I remained in Berne four days, and had an excellent opportunity to become familiar with the work in the surgical wards, but will only describe the operations of one forenoon to show what a man like Kocher can do in 4 hours The operations began at 7 A M, and a little after 11 o'clock the whole work was done The world knows that Kocher's great specialty is strumectomy He astonished us all a few years ago when he reported 101 cases of strumectomy at the time when he first called attention to the danger which follows complete extirpation of the thyroid gland, as in quite a number of his cases in which the whole organ was removed a condition allied to cretinism followed, which he described under the term cachexia strumipriva He has now performed the operation more than 300 times, and his results have been so good that in 100 consecutive cases he has not had a single death He looks upon excision of struma as one of the safe operations of surgery I was very anxious to see the master of this operation confronted with a difficult case Two cases were in the hospital awaiting strumectomy, and he selected for my special benefit the one which was expected to present the greatest difficulties

The patient was a woman about 40 years old, who had had a large neck since childhood For a number of years the tumor has been growing more rapidly, until at present it has reached the size of a fist, and is giving a great deal of difficulty in breathing, especially when the patient undergoes unusual exertion She was very anæmic The tumor was located almost centrally over the neck, but did not dip behind the sternum No fluctuation Chloroform was the anæsthetic, and was continued throughout the operation The external incision was made over the centre of the tumor, and obliquely across the neck Even before the tumor was reached a number of vessels had to be divided between the forceps The veins all around and beneath the tumor had walls as thin as paper, so that attempts to ligate them failed, and venous hæmorrhage had to be guarded against by compression Another difficulty from these thin-walled veins was that many times large trunks were accidentally injured in the blunt separation of the tumor from its surrounding tissues The extirpation lasted over an hour, and all the forceps which the institution possessed, some 60 or 70 were brought into use, and at least another dozen would have been used had they been accessible The patient, already anæmic, lost considerable blood during the operation, and after all vessels were ligated and the wound sutured, and as the dressings were to be applied, she passed into a condition of collapse, with rapid almost imperceptible pulse, dilated pupils, and extremely pallid countenance The operator at once had the patient's head lowered and the lower extremities elevated, and at the same time injected ether hypodermatically As

the heart did not respond he at once prepared for saline intravenous infundation A saline solution 6 1000, temperature of the blood, was used The median basilic vein was exposed, opened and a glass tube, connected with a rubber tube and an ordinary glass funnel, was introduced into the vein and tied firmly with a ligature The fluid was allowed to flow very slowly, and a little more than a litre was introduced before the contractions of the heart became firmer and the pulse fuller When this was done the pupils contracted, the patient became conscious and the operation was suspended The dressing was now applied, and the patient put to bed with the head low and artificial heat about the periphery of of the body An hour later the patient was conscious, the pulse still rapid but with a fair volume Under such circumstances a man's courage is put to the severest test, but Kocher did not show the least excitement, and performed the transfusion as deliberately as though he was demonstrating the operation before his class on a cadaver The day after the operation I examined the case with Kocher, and though the pulse still remained rapid, all other indications were favorable, and it is more than likely that this patient, snatched from almost certain death by prompt treatment, will ultimately recover

Immediately after this patient left the operating room a boy 14 years old was brought in suffering with tubercular synovitis of the left elbow joint Kocher has also had an unusual experience with excision of the elbow One of his assistants has collected all of his cases of excision of the elbow-joint, some 100 in number, and will in the near future publish the results in one of the medical journals Kocher always makes a longitudinal incision over the centre of the olecranon process, and joins this with a shorter one at a right angle in the direction of the radio-humeral joint, so as to have full access to the joint The insertion of the triceps muscle is preserved by keeping close to the bone in separating the soft tissues from the olecranon process The capsule is thoroughly extirpated, and as much of the bone with forceps and sharp spoon as is necessary, preserving in the case of children, whenever practicable, the epiphyseal cartilage In this case a small detached sequestrum was found in the trochlea, showing conclusively that the disease began in the humerus All small vessels were secured as they were divided, and the dressing was applied before the Esmarch's constrictor was removed No splint was used as the copious dressing and careful bandaging secured adequate immobility in proper position for the resected joint

The third case was an arthrectomy for primary tuberculosis of the synovial membrane of the knee joint in an adult female The usual horse shoe incision was made, but this was joined by another incision extending along the inner margin of the patella The cutaneous flaps were dissected back, and the bulging capsule of the joint came into view The capsule was incised from one side, and a longitudinal incision dividing the capsule on the opposite side of the patella enabled the operator to dislocate this bone to either side, thus rendering the joint well accessible in all its remote corners after it was partially dislocated by forcible flexion of the leg The greatest care was taken to remove every particle of the diseased capsule with knife and scissors, and where these were inapplicable the sharp spoon was vigorously used After the joint was thoroughly cleared the patella was placed in its proper position, two openings made on either side for drainage, the wounds sutured, a copious dressing applied, and the limb placed upon an interrupted posterior splint with foot board

Thus ended the eventful forenoon I gladly accepted an invitation to dinner sent by Mrs Kocher to the hospital After a substantial and elegant meal we rested for several hours in the beautiful garden behind the house, and the mental feast that awaited us here, if anything, surpassed our bodily enjoyment Kocher has a small laboratory in the Pathological Institute in charge of Dr Cavel, his private assistant, who has done some excellent work here

Cavel has been studying in a systematic manner the diagnostic value of implantations of tubercular material in animals, mainly guinea pigs Granulation tissue from tubercular joints invariably produces acute, diffuse tuberculosis, and death in from 5 to 6 weeks The course of the disease in the animal is typical at the point of inoculation a hard nodule appears first, the result of traumatic response on the part of the tissues around the graft Next a lymphatic gland becomes enlarged in the immediate vicinity of the inoculation, which is done in the flank, consequently the glands in the groin enlarge first Often a whole chain of lymphatic glands can be felt in the groin At a later stage the glands in the axilla become affected At the post-mortem examination it is always found that of the internal organs the spleen becomes affected first, then the liver and lungs, but usually the disease is so diffuse that scarcely an organ remains exempt When the diagnosis cannot be made between tuberculosis and syphilis, either clinically or by the microscope, inoculation always decides the matter When the lesion is tubercular the animal always becomes tubercular and dies When it is syphilis the inoculation is harmless and the animal remains well I examined a number of the animals and satisfied myself of the truth of these assertions So far only one animal that was inoculated with tubercular matter has lived for 5 months, and in this case a large abscess formed at the point of inoculation a few weeks after the operation Examination of the contents of the abscess showed abundant bacilli tuberculosis A gland in the groin remains enlarged, and the disease, if not arrested by the suppurative inflammation, may have become latent

I reached Geneva just in time, as the evening I arrived Professor Julliard sent me word that he would enucleate a struma at 9 A M the following morning I met the genial and courteous Professor at the appointed time in the Hopital Cantonal, and I saw the case he was going to operate on The patient was a young man with a very short thick neck, and suffering a good deal from dyspnœa from a retro-

sternal struma Externally the swelling could hardly be seen except when the head was thrown back, in this position a soft swelling could be felt just above the manubrium sterni About 21 students, including 3 females, had gathered in the amphitheatre to see the operation

The operation was begun without an anæsthetic, but the patient was so restless and noisy that chloroform had to be given An incision was made in the median line of the neck and carried as far as the sternum, this exposed a number of very large veins, which were isolated with the operator's own curved forceps, and divided between two ligatures The muscles over the tumor were partly cut and partly separated As soon as the capsule of the tumor was reached enucleation was begun by a blunt curved scissors and the finger During these manipulations the cyst was ruptured, and the empty sac was drawn forwards and carefully separated A number of the bleeding points required ligation The cyst seemed to spring from the isthmus of the gland After the cyst was removed two more tumors were felt embedded in the right lobe of the gland, these were removed through an incision along the anterior border of the sterno cleido-mastoid muscle in a similar manner The bleeding, especially from the cut and torn surface of the gland, was quite profuse, and required many ligatures for its arrest The wounds were dusted with iodoform, drained, and the edges sutured together The suturing was done with a large curved needle fixed in a handle which is passed through the tissues on both sides and then threaded by an assistant That the assistant did not always hit the eye of the needle with his thread of catgut as unerringly as the operator expected and demanded was not the fault of the assistant, but of the needle Juillard ought to deposit this needle in one of the antiquity shops of Geneva, and some enterprising Hebrew would find for it ready buyers who would cherish it as a relic of Pompeii or some other ancient and defunct city The dressing that the wound received deserves mention It was first covered with protective silk, next by half a dozen large sponges previously made aseptic by being kept in carbolized water, next came a compress of gauze large enough to cover the head and half of the chest, this was again covered by absorbent cotton, and lastly ordinary cotton to fill up spaces, and the last layer was impermeable paper All these things were retained with gauze rollers, and lastly a rubber bandage When the whole thing was done the patient looked like an Egyptian mummy

The spray is still used in this clinic, and carbolic acid is preferred for an antiseptic solution Juillard has the best collection of instruments I have ever seen in a hospital, and when I called later at his house I admired his own private collection, which is not as large, but very select He has also quite a large library, and from the way in which pamphlets were kept and books arranged he keeps his library for useful rather than ornamental purposes I think he is a diligent reader His contributions to literature have been many and valuable His wards contain 120 beds, but during the summer months, from the latter part of April to October, the patients live in tents and have the full benefit of open country air Each tent or barrack has room for about 20 patients During this time the rooms in the hospital remain vacant, and can be thoroughly prepared for the next winter I think this plan should be more generally adopted, as it does not involve much expense Juillard told me that all the tents did not cost over 6000 francs

And now I am at the terminus of my journey, and will begin to retrace my steps to-morrow I am perfectly satisfied with the results of my trip, as it has afforded me an opportunity to complete a part of my education which could have been done in no other way I have seen many things, good and bad We often learn as much by looking at the shady as the sunny side I have accumulated enough material to keep my thoughts busy not only for months but for years N SENN

DOMESTIC CORRESPONDENCE

THE BURTON CASE

Dear Sir —In THE JOURNAL of September 3, the paper of Dr W T Parker is mainly devoted to discussing the question whether the two bullet wounds described could have been self-inflicted, and if they were, which was first in point of time? In regard to the last question the consensus of opinion seems almost unanimous in favor of the position that the heart wound would be so instantaneously fatal as to preclude the idea of that being the primary injury

As the only method of determining such a question is by the observation of the results of similar injuries, under conditions favorable for watching the entire process, it follows that any fact so observed, bearing directly on the issue, will possess a certain value, possibly sufficient to warrant its record This consideration must therefore be the apology for a brief narrative of a case recently within the cognizance of the writer

During a quarrel in a saloon one of the parties, a young man, was stabbed in the breast with a broad bladed dirk knife, which penetrated the right ventricle, making a transverse wound one inch linear measurement in extent After being struck the wounded man ran out of the door along a platform in front of the building, jumping to the ground a distance of 3 or 4 feet and continuing to run till he reached his boat, drawn up on the beach and distant from the saloon about 100 feet As he endeavored to push the boat into the water he fell unconscious His comrades lifted him into the boat and rowed to the opposite shore, a distance of 35 rods He was lifted out of the boat and carried a few rods and laid upon the ground He was still unconscious, but having been made to swallow a little brandy, he aroused into partial consciousness, and attempting to rise, fell back dead He lived after the receipt of this injury not less than 25 minutes, and would have lived longer had he been let alone There can be no doubt that this man retained consciousness and physical strength

after he was stabbed for a period of time sufficient to have emptied the contents of one pistol at least

This case, therefore, so far as it has any relevancy to the questions propounded by Dr Parker, corroborates the dictum of Prof D H Agnew Very truly,

ARTHUR YOUNG, M D

Prescott, Wis , September 6 1887

COCAINE SOLUTIONS

Dear Sir —When I first began the use of cocaine my plan was to have 6 or 8 ounces of a 4 per cent solution prepared and keep it in my office, applying when necessary, until it was exhausted I soon began to notice that at times its effect would be perfect, at other times seriously disappointing On one occasion a patient came in for the introduction of a bougie I injected a small quantity of the solution (which was the last of my bottle) into the urethra, retaining it some minutes, and then carefully introduced the instrument He complained of great pain, feeling no relief from the cocaine Two days later he returned for the same operation In the meantime my bottle had been replenished with a *fresh* solution, which I injected as before, when I introduced the instrument, without pain, the patient expressing himself as not feeling it at all I began to reflect Why should cocaine fail at one time and succeed at another? I could see no difference in the two operations except one was with a fresh solution, the other perhaps ten days old After this, in order to test the matter, I made a number of experiments on different cases, and was so thoroughly satisfied that I no longer keep the solution on hand, but instead the crystal muriate of cocaine, and prepare my solutions for each case, often without making an exact per cent, but simply mixing with a little water without weighing

The results of these experiments may be summed up as follows

1 Solutions of cocaine, even though admixed with boracic acid, gradually lose their anæsthetic powers

2 Freshly made solutions, applied immediately, will never fail to give the most satisfactory results

3 When freshly prepared, much weaker solutions will be needed than when kept on hand A 2 per cent strength is as effectual (when fresh) as a 4 per cent two or three weeks old

4 Fresh solutions are not productive of destructive inflammation to the eye, as has been attributed by some to older solutions

It would probably be well to state, in conclusion, that in these experiments, its use has been chiefly confined to the male urethra I always increase the strength of the solution in proportion to the pain to be produced If a sensitive stricture is to be cut I use a strength of from 10 to 20 per cent , if an examination is to be made or a bougie introduced a 2 to 4 per cent answers every purpose

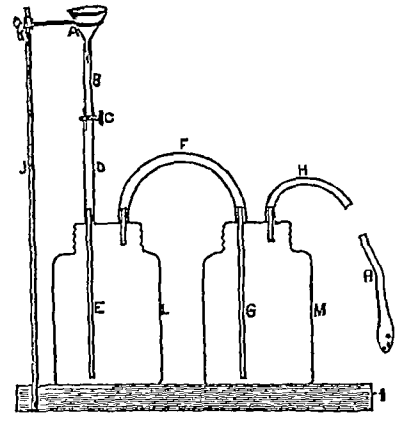
NEW INSTRUMENTS.

APPARATUS FOR GASEOUS INJECTIONS

BY M E CONNELL, M D ,

PHYSICIAN TO THE MILWAUKEE COUNTY HOSPITAL

This apparatus does away with the gas reservoir or rubber bag It can be extemporized very quickly and cheaply by any physician possessed of two fruit jars, a small piece of rubber tubing, a hard rubber cock and a glass funnel I prefer it to the original apparatus To physicians remote from instrument shops it may prove useful



Solution X—is composed of	
Sulphuric acid c p	7 ozs
Water	2 pts
Solution Y—is composed of	
Sodium bicarbonate	1 oz
Water	4 ozs
Solution Z— is composed of	
Calcium sulphide	5 grs
Sodium chloride	5 grs
Water	22 ozs

Two ounces (2 ozs) of sol x is allowed to drop slowly (through A) into sol y (in L), when carbonic acid gas is generated, which passes through sol z (in M), and in combination with sulphuretted hydrogen is conveyed to the rectum through the tube H

BOOK REVIEWS.

LEITFADEN ZUR ANTISEPTISCHEN WUNDBEHANDLUNG, mit Rucksicht auf ihren gegenwartigen Standpunkt Von GEHEIMRATH VON NUSSBAUM in Munchen Funfte, ganzlich umgearbeitete Auflage 8vo , pp xx, 308 Stuttgart Verlag von Ferdinand Enke 1887

GUIDE TO THE ANTISEPTIC TREATMENT OF WOUNDS By GEHEIMRATH VON NUSSBAUM Fifth, completely revised edition Stuttgart Ferdinand Enke 1887 Chicago Koelling, Klappenbach & Kenkel

Our readers will remember that in a very recent letter Dr Senn said that this book had done "more towards the general adoption of antiseptic principles in the treatment of wounds than all the rest of the German literature combined " That it is appreciated outside of Germany is proved by the fact that

it has been translated into five languages, and the number of editions—five—shows that it is thoroughly appreciated at home In 1880 the author said, in a lecture, that a physician who ignored antisepsis and had a patient die of pyæmia deserved to be mulct in damages—and for this he was roundly abused at the time His statement is still more true to day

On account of the conciseness of this book, it would be difficult to do more than give a synopsis of the table of contents in the space at our command The volume opens with an introduction on the present standpoint of wound treatment, which is followed by a chapter on "Infection, Intoxication (Fibrin Ferment, Fat Embolism)," of 17 pages The third chapter, on "Accidental Wound Diseases," occupies 21 pages, and treats of Inflammation and Suppuration, Erysipelas, Diphtheria, Hospital Gangrene, Sepsis, Septicæmia, Ichoræmia, Pyæmia, and Pyosepthæmia The fourth chapter is devoted to a consideration of the *Precautions against Infection of Wounds—the most important Part of the Treatment*, and one who thinks that he knows all about antiseptics and antiseptic dressings and materials should read it—and find that he is mistaken

Apparently on the principle that example is better than precept, the author shows the reader, as clear as may be with words, a number of *Examples of Antiseptic Operations* in a chapter of 32 pages These examples are an operation for multilocular ovarian cyst, the record of which occupies 14 pages, amputation for crushed knee, osteotomy by MacEwen's method for genu valgum, and an antiseptic operation in the country, complicated luxation of humerus, resection of head of humerus Other examples are also given in the chapter on "Antiseptic Dressings" wound of the head, hare lip, operations for trigeminal neuralgia, for struma, for wound of the neck, involving the trachea and œsophagus, for cavernous tumor over the clavicle, for chest wound and empyema, for cancer of the breast, for penetrating wound of the abdomen, for pelvic phlegmon, for varicose ulcer of the leg, incarcerated hernia, cancer of the rectum, cancer of the uterus and vagina, compound fracture of the legs, old fracture of the patella, treated by suture, operation for club foot, nerve-stretching for neuritis ascendens, dressing for burn of the chest, and description of the treatment of fungous inflammation of joints by the spoon

The most wonderful thing about this book is the immense amount of information that has been put into it Could all authors imitate the style of Prof Nussbaum we would have more valuable books, and fewer pages Certainly we have but one book in our language, on a similar subject, which can be at all compared with it—Stephen Smith's "Operative Surgery"

MISCELLANEOUS.

POISONOUS HAM.—Recently at Carlisle, England, several persons were seized with dangerous symptoms of poisoning after eating some of an apparently good ham Dr Philip has from the ingesta in some of these cases obtained fairly pure extracts, and their physiological effects have been studied in frogs and in the human subject The results of these experiments indicated that a poison of some potency had been present The poison was not detected by the ordinary methods of analysis, and some of its features suggested relationship with the group of bodies relatively grouped as ptomaines or cadaveric alkaloids It was probably traceable to some form of fermentation which, in turn, possibly depended on certain organisms which were discovered in the foods examined The ascertained presence of such bodies gives important indications of treatment With regard to the organisms which had been discovered in portions of the ham in question, certain preliminary difficulties had presented themselves in the process of staining, as probably some of the ingredients used in the process of curing prevented the tissues from receiving the stain so readily as usual When sufficiently exposed the sections were found to contain micrococci These were in groups both at the edge of the section and between the muscular bundles They appeared to bear close relation to the tissues The organisms were quite different from those usually discoverable in tainted ham From their reaction with staining solutions, it was likely that the organisms had obtained access to the ham after it was cooked, and it is suggested that the condition of the cellar in which the hams had been kept subsequent to cooking affords a possible explanation of their appearance

LONDON SCHOOL OF MEDICINE FOR WOMEN.—After being remodeled and extended, the London School of Medicine for Women has had a most successful session The older portion of the school comprises a dissecting room, physiological and chemical laboratories, an excellent library, there is also a small but valuable anatomical and pathological museum, the latter containing an important collection of gynecological preparations Students do not reside at the school, but for such as require it there is a hall of residence in connection with it, superintended by a committee The only conspicuous lack of this rising young institution is a hospital of its own for the clinical instruction of its students For the first three months of its existence this was a very formidable difficulty A hospital of 150 beds or upwards is absolutely indispensable for a complete medical course, and for three years not a single institution in London would admit female students In 1877, however, the Royal Free Hospital, not very far from the school, opened its wards Still there remained another drawback, no English Board of Examiners would admit them to its examinations They could take Continental diplomas, and those of King and Queen's College of Physicians of Dublin, but not a single Board would in England admit them until in June, 1877, the London University decided that women should thenceforth be permitted to present themselves for examination for degrees There are now between 60 and 70 students at the school, and a complete list shows that at the present time there are 55 registered medical women, all duly qualified medical practitioners

THE SUBSCRIPTIONS TO THE COMMEMORATIVE MEDAL of the Ninth International Medical Congress have proved nearly sufficient to cover the necessary expenses of engraving the die, striking the medal, furnishing a proper case, and mailing the completed medal to the subscribers That all members of the Congress, however, may have an opportunity of possessing this memento, those who have not subscribed can yet do so any time within this month by forwarding the cost, $5 00, to Dr J M Toner, 615 Louisiana Ave, Washington, D C

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM SEPTEMBER 3 1887, TO SEPTEMBER 9, 1887

Major C C Byrne, Surgeon, detailed as a member of the Army Retiring Board in Washington City, vice Capt Washington Matthews, Asst Surgeon, relieved Par 2, S O 208, A G O, September 7, 1887

Major R M O'Reilly, Surgeon, U S Army, ordered to proceed to Ft Niagara, N Y, on public business, and upon completion thereof, to return to his proper station, Washington, D C Par 10, S O 205, A G O, September 3, 1887

First Lieut W B Banister, Asst Surgeon, granted leave of absence for one month, with permission to apply for extension of one month, to take effect upon arrival at Ft Lowell of Asst Surgeon J B Girard Par 4, S O 91, Hdqrs. Dept of Ariz, August 29, 1887

Case 179 Dr Douglas, of New London, has treated the patient by electrolysis, when no instrument would pass, and improved him so that the natural course of the urethra was re established to No 23, and full power of his bladder

In presenting this report of cases of urethral strictures, treated by electrolysis and a tabular statement of a second series of 100 cases, my object is to record facts from clinical experience in private practice, and by presenting a respectable number of cases, to establish reliable statistics which as a record will assist the study of the subject and fortify the successful results obtained previously I have practised electrolysis in the treatment of urethral stricture, over 18 years, and have from time to time reported cases Many other surgeons from different parts of the world, including countries in Asia, have substantiated the good result of such treatment, so that at present we could collect easily 1,000 cases, which record should establish the value of my method But I am not aware that any other person besides myself has contributed to the statistics 200 cases from private practice The difficulty consists in this, that in order to use a case for reliable statistics, the patient must (1) have given a true history and address of himself, (2) remained under treatment a certain time, (3) followed advice and attended regularly to appointments, (4) remained under observation after being dismissed, and been accessible for further information Cases of dispensary patients, as a rule, are worthless for statistics, and even in private practice only a small percentage can be utilized for an honest record Therefore it will be seen, that it is very difficult for one practitioner to collect 100 cases for reliable statistics

No Relapse —My paper of the first 100 cases was presented to this section at the meeting in 1883— and differs somewhat from this second series One principle feature was, to show that no relapse of the malady occurred after the stricture has been cured by means of the electrolysis As the meaning of the word "cure" may be interpreted differently by some than by others, I will be more explicit by defining my meaning, viz no contraction of the calibre of the urethra takes place, and after the patient has been dismissed as well, to his own satisfaction, the same number of sound or catheter which was used the last time in treatment, would easily pass, after a year or even many years When the value of electrolysis had been proven by reported cases, and even by my article of "10 years experience, etc," some sceptics still objected, claiming that not enough time had elapsed between the treatment and the after observation To meet that objection I prepared the paper of "Tabular Statistics of 100 Cases of Urethral Stricture, Treated by Electrolysis without Relapse " These 100 cases were naturally not consecutive cases, but collected from consecutive cases for the purpose, and had to meet the following conditions

(1) The patients being under treatment regularly, and for a reasonable time, (2) that they were to be discharged as cured, or at least so improved, that the patients were content with the result, and did not wish any further treatment or improvement, (3) they were to be cases that were heard of afterwards by reliable information, mostly by re examination of the family physician or by myself Some of these patients came repeatedly for such an re examination (4) That a *reasonable* time had been allowed between the discharge when cured and the re examination, which in these cases was resp from 3 to 11 years

The proof of no relapse was, that the same number of sound was used in the re examination, which passed the last time at the close of the treatment, *i e*, if the calibre of the urethra was enlarged to a number 26 French, the same number 26 passed again after resp 3 to 11 years Some unfriendly critics jeeringly said, "it was a remarkable point in Dr Newman's cases, that they were, every one of them, successful " But these critics overlook the fact, that in the selection of these 100 cases, the first essential point was, that they were discharged as cured, in order to see whether or not a relapse would take place I have stated all these facts distinctly in my former paper, and those sceptical critics have overlooked the facts, and therefore have been unjust

Selection of Cases —The present record of the second series of 100 cases, which I have the honor to report to day is collected in a different way It consists of the experience of the latter few years, the narrative of almost consecutive cases taken from my note book, relating all such cases, which have remained long enough under treatment to warrant a result, and in which the necessary information has been furnished and recorded, on the other side omitting cases, which have not been long enough under treatment, or only seen without treatment, and in which the record is insufficient In this report I have on purpose omitted the word "cured," because there is a diversity of the meaning cure The patients were dismissed or stopped treatment themselves, when they felt comfortable and well, had a calibre of the urethra which enabled them to void freely a good large stream, and if wanted could exercise sexual intercourse

The result of such treatment is marked under the heading "sequel and calibre of the urethra when discharged " The number of the last electrode used, is stated according to the French scale

In recapitulating we find that

Strictures which admitted no instrument were enlarged from No 17 to 28 resp
Strictures which admitted a No 2 instrument were enlarged to No 23
Strictures which admitted a No 6 instrument were enlarged from No 17 to 28 resp
Strictures which admitted a No 7 instrument were enlarged to No 23
Strictures which admitted a No 8 instrument were enlarged to No 28
Strictures which admitted a No 9 instrument were enlarged from No 23 to 28 resp
Strictures which admitted a No 11 instrument were enlarged from No 26 to 28 resp
Strictures which admitted a No 12 instrument were enlarged from No 24 to 28 resp
Strictures which admitted a No 13 instrument were enlarged from No 24 to 28 resp
Strictures which admitted a No 14 instrument were enlarged from No 20 to 30 resp
Strictures which admitted a No 15 instrument were enlarged from No 22 to 28 resp
Strictures which admitted a No 16 instrument were enlarged from No 23 to 26 resp
Strictures which admitted a No 17 instrument were enlarged from No 23 to 28 resp

Strictures which admitted a No 18 instrument were enlarged from No 25 to 32 resp
Strictures which admitted a No 20 instrument were enlarged from No 25 to 30 resp
Strictures which admitted a No 21 instrument were enlarged from No 25 to 32 resp
Strictures which admitted a No 23 instrument were enlarged from No 26 to 32 resp
Strictures which admitted a No 25 instrument were enlarged from No 30 to 32 resp

The result of the enlargement of the calibre of the urethra varied according to circumstances, as necessities, wishes of the patients, time allowed for treatment, nature of the stricture, complications, general condition as occupations, vices or virtues of the patients But results must be considered very good, even by chronic grumblers, if a calibre of a urethra can be enlarged to a No 28 French, when at the first visit no instrument would pass, and experts have tried in vain before In some cases the family physician has tried for weeks, in others, celebrated professors were given chances, without being able to instrument, and the disposition of the cases the advice of perineal section In some cases advice by the family physician was accompanied a written introduction to a first class operator, tc In all such cases, when no medical hand could pass the stricture with an instrument, it was passed successfully by the power of the "electrolysis," which acted as a chemical absorbent, and not as a dilator, as some kind friends have suggested If in these cases dilatation could have been used, why did the experts and surgeons not do it? In one case mentioned in a former paper, a surgeon whose skill in using instruments is undoubted, was unable at nine trials to pass any instrument through the stricture, which a doctor in a New Jersey village, probably not as skilled in the manipulation of instruments, succeeded with electrolysis on the very next day All these are facts which can be verified by reliable witnesses, and there can be no doubt that the electrolysis did the work, which could not be done by pressure or dilatation

The duration of the strictures at the time the patients presented themselves for treatment varied from 1 month to 30 years, and in recapitulating we find

Two cases of 1 month standing, 2 cases of 3 months, 2 cases of 4 months, 4 cases of 6 months, 1 case of 9 months, 3 cases of 1 year, 10 cases of 2 years, 6 cases of 3 years, 6 cases of 4 years, 11 cases of 5 years, 6 cases of 6 years, 5 cases of 7 years, 4 cases of 8 years, 4 cases of 9 years, 4 cases of 10 years, 2 cases of 11 years, 1 case of 12 years, 2 cases of 13 years, 1 case of 14 years, 2 cases of 15 years, 1 case of 16 years, 2 cases of 18 years, 1 case of 19 years, 7 cases of 20 years, 2 cases of 21 years, 2 cases of 25 years, 2 cases of 26 years, 1 case of 30 years, 4 not known

To make the recapitulation of the different points in these cases more interesting, we will now compare both series of 100 cases What was the percentage of single to multiple strictures?

In the *first* series of 100 cases we find 42 single and 58 multiple strictures with a total of 189 strictures In the *second* series of 100 cases we have only 21 single, 79 multiple, with a total of 230 strictures

There is a striking difference between the two series, and it seems that the average appearance is more correctly given by the first figures, so that we may expect nearly one-half of patients presenting themselves, having single strictures The increase of multiple strictures in the report of last years, may arise from the fact, that more bad cases were transferred to me The number of strictures in one individual we find as follows

	First 100	Second 100	Average in 200
1 stricture in	42	21	31½ cases
2 strictures in	34	43	38½ "
3 " "	17	26	21½ "
4 " "	5	7	6 "
5 " "	2	1	1½ "
6 " "	0	2	1 case

The location of the strictures was found in all parts of the urethra, from the meatus to more than 8 inches from it, as follows

Location of Strictures in	1st 100 Cases	2d 100 Cases	Average in 200 Cases
At the meatus or less than 1 inch from meatus	8	9	8½
At 1 inch or less than 2 inches from meatus	12	12	12
At 2 inches or less than 3 inches from meatus	31	24	27
At 3 inches or less than 4 inches from meatus	29	41	33
At 4 inches or less than 5 inches from meatus	42	30	36
At 5 inches or less than 6 inches from meatus	37	46	41
At 6 inches or less than 7 inches from meatus	24	40	32
At 7 inches or less than 8 inches from meatus	0	20	10
At 8 inches or more from meatus	10	8	9

SITUATION —The greatest number of strictures were from 4 to 6 inches in the first 100 cases from 5 to 6 inches in the second 100 cases or in the first part of the urethra In the membranous part, 10 per cent, first 100, 20 per cent second 100, average in 200 cases, 15 per cent. In the *prostatic part*, 5 per cent first 100, 8 per cent. second 100, average in 200 cases, 6½ per cent

This combined statistic of 200 cases confirms the observations made at the report of the first series, that strictures appear in every portion of the urethra, about 10 per cent in the membranous, and about 5 per cent in the prostatic portion, some of the latter were of traumatic origin It seems to be a mistake, to believe that there are no strictures in the prostatic portion of the urethra, and that the largest number are situated within 3 inches from the meatus

Seances, intervals and time of treatment average exactly alike in both series reported From 1 to 10 operations, in some cases even more were necessary, from which fact one may draw the conclusion, that the average number of séances was 5 to 6 for each case The treatment in each case averaged 2 to 3 months Long intervals between the séances, and weak currents are rules to which I still adhere, and which I cannot impress too strongly on operators, as most important points in these operations The intervals ought to be once a week or more, but in case of necessity may be shortened, each séance lasted from 2 to 10 minutes, I do not like to prolongate it more, except for good reasons The electric current is from 3 to 5 milliampères of a good galvanic battery, having a steady current, which is equal to from 6 to 10 cells Precision and measurement of

the electric current are desirable, if a good galvanometer can be procured

Observations —The length of time patients were under observation after treatment differs widely in the two series, for good and natural reasons The patients recorded in the first series were under observation from 3½ to 11 years, which is an average time to from 6 to 7 years in each case I have shown above the object and result of such observations, and certainly it has been proven that during years after the treatment the calibre of the urethra, when once sufficiently enlarged, or cured if you please, did not suffer any contraction This principle or effect of the electrolysis is also proven in the second series of 100 cases, but not in such a striking degree This is most natural for several reasons These cases were all treated lately, within a few years, some remaining still under treatment or observation, therefore the record of observation could not have been longer than a few years Next the cases were not selected, but reported almost as consecutive cases, as found in the note book There is no claim, that these cases were all cured, the record speaks for itself and shows how far they were improved, or a good reason why they were not more improved Even in this series in most cases a reasonable time had elapsed for observation, and many re-examinations have shown that no contraction of the urethra had taken place These observations comprise a time between 3 months to 5 years, the largest percentage of observations were made from 1 to 3 years A small percentage of these cases were not heard from again, but as they all left off treatment, when the calibre of their urethras was resp of a No 25, 28 and 32 size French, it is presumable that they remained well, and that such was the reason of their non appearance again

For other information concerning electrolysis, I refer to my former paper, published in THE JOURNAL, April 25, 1885, and its continuation, "Tabular Statistics of 100 cases of Urethral Stricture Treated by Electrolysis," in the *New England Medical Monthly*, August, 1885 There will be found the definition of electrolysis, the theory, as also the action of the poles, practical experiments and demonstrations, the *modus operandi* and instruments used The latter are still more minutely described in my article "The Armamentarium for the Treatment of Urethral Stricture by Electrolysis, with a *resume* of the Operation," which appeared in the *Medical Register*, Philadelphia, February 19, 1887 While these details are omitted here, in order to avoid repetitions, it may be useful to give short and practical rules for the performance of the operation, as a safe guide for practitioners who wish to adopt the treatment of electrolysis in stricture of the urethra

Recapitulation of general rules

1 Any good galvanic battery will do, which has small elements and is steady in its action, the twenty-cell battery, carbon and zinc elements is an excellent instrument, and particularly sufficient for the beginner

2 The fluid for the battery ought not to be used too strong

3 Auxiliary instruments, as galvanometer, etc, are important to the expert, but not necessary for the beginner

4 For the positive pole a carbon electrode is used, covered with sponge, moistened with hot water, and held firmly against the cutaneous surface of the patient's hand, thigh or abdomen

5 For the absorption of the stricture the *negative* pole must be used

6 Electrode bougies are firm sounds insulated with a hard baked mass of rubber The extremity is a metal bulb, egg shaped, which is the acting part in contact with the structure

7 The curve of the bougie is short, large curves are mistakes

8 The plates must be immersed in the fluid before the electrodes are placed on the patient, and raised again after the electrodes have been removed

9 All operations must begin and end while the battery is at zero, increasing and decreasing the current slowly and gradually by one cell at a time, avoiding any shock to the patient

10 Before operating, the susceptibility of the patient to the electric current should be ascertained

11 The problem is to absorb the stricture, not to cauterize, burn or destroy tissues

12 *Weak currents at long* intervals

13 In most cases a current of 6 cells, or from 2½ to 5 milliampères, will do the work, but it must be regulated according to the work to be done

14 The *seances* should be at intervals not too frequent in succession

15 The best position for the patient to assume during the operation is that which is most comfortable for *himself and the operator* I prefer the erect posture, but the recumbent or others may be used

16 Anæsthetics I like to avoid, I want the patient conscious, so that he can tell how he feels

17 Force should never be used, the bougie must be guided in the most gentle way, the electricity alone must be allowed to do the work Avoid causing hæmorrhage

18 During one *seance* two electrodes in succession should never be used

19 All strictures are amenable to the treatment by electrolysis

20 Pain should never be inflicted by the use of electrolysis, therefore it should not be applied when the urethra is in an acute or even sub-acute inflammatory condition

21 The electrode should not be greased with substances which are non conductors, and would insulate

Objections —In reality there can be no valid objections to the method of electrolysis in the treatment of urethral strictures, and those which have been raised from time to time come either from men entirely ignorant of the first physical laws of electricity, or from such who had a personal interest or feeling in the matter To the latter class in the opposition belong some surgeons of high standing, who are wedded to the knife, have not tested the electrolysis, and hence are opposed to any innovation Most of such objections are entirely unfounded,

based on false theories, or are too trivial and even ludicrous to be considered Some have even the stamp of mis statements purposely made Here for instance is one, which we find in a modern text-book on surgery "Electrolysis, as a means of cauterization and dilatation recommended recently, is painful, uncertain, and liable to be followed by peri-urethral abcesses It possesses no compensating advantages which entitle it to any further notice" The author of this strong language of condemnation had no knowledge nor experience in any kind of electricity

His statement is either the consequence of ignorance or made to mislead, because he ought to know, that electrolysis is not a cauterization nor a dilatation, on the contrary I have warned always against cauterization, and stated over and over again, that electrolysis is not a dilatation, but the process of decomposing a compound body by electricity, a galvanic chemical absorption It is further false that it is painful, uncertain and liable to be followed by peri-urethral abcesses On perusal of my rules and records, it will be found that pain should never be inflicted, and that the process gives certain positive results During my large experience with urethral strictures, I never yet have seen a peri urethral abcess follow the electrolysis, and all such abcesses which have come under my observation ante dated the electrolysis And on the other hand, how cunning (which may be accidental) is the condemnation of electrolysis worded by the great surgeon, leaving a hole to creep out If he is taken to task for his sentence, he may say he condemns electrolysis only as a cauterization, but as a decomposing agent it is all right Why did he not say it? I leave it to any impartial judge, if such a sentence in a text-book does not mislead the masses instead of instructing? A man who writes a text book for instruction, ought to stand by the truth and be silent on matters he does not know

One friend objects to the treatment because it does not always cure a prostatitis or any other discharge Of course, it does not always, and discharges will only be cured if their existence is caused by the stricture, but if there are granulations, or other causes, our electrolytic treatment has nothing to do with it Some are aggrieved to hear, that to succeed, it is necessary to understand electricity and the handling of the genito-urinary instruments Now there is scarcely a profession, business, or even common labor, which can be exercised without an apprenticeship, and in any vocation expertness is needed to be useful The same objection could be raised to any operation, or even to the practice of medicine If operators, who are unskilled or careless fail in their undertakings, it does not condemn an acknowledged good operation A London surgeon does not like the long intervals between *séances*, without giving any reason for it If necessary, he may operate at shorter periods, as I have shown in the report of cases, that I have done so in intervals of 2 days My recommendation of longer intervals is made for the convenience and pleasure of the patient, who is generally made comfortable after 1 operation, and for that reason I consider long intervals rather an advantage One of my distinguished friends, who is most persistent in his opposition to my methods, argues as follows

Electrolysis is heat, heat burns, burns make cicatrices, cicatrices make every stricture worse, *ergo*, *electrolysis is no good* Now that gentlemen ought to know better, after having read my articles on the subject, and heard my explanations I distinctly advise, always practice, and insist upon weak currents of from 2½ to 5 milliampères, so that the electrolysis acts as a chemical decomposition by absorption, which *never* burns nor destroys tissues

If some gentlemen use too strong currents, or the positive instead of the negative pole, they make gross mistakes, must necessarily fail, destroy tissues, and ruin their patients If professors and others have made such mistakes and failures, it is to be lamented, but does not harm the reputation of a good method, approved by acknowledged successes all over the world in a very great number of cases

In England very good results have been reported similar to my own And there also similar objections have been raised, particularly at the discussion of the Royal Medical and Chirurgical Society, when Drs W E Steavenson and W Bruce Clark read a paper on the subject To their good results of electrolysis it was objected, that their cases were of too recent a date, and their number of cases have not reached such dimensions as to place it on record as accomplished facts These gentlemen of high standing in the profession known as experts in electricity who have done excellent good work, were then treated exactly as I was, when I had practiced the electrolysis only a comparatively short time But, when my 100 cases were alluded to, in which no relapse occurred after an observation and re examination from 3½ to 11 years, the objection then was, that such statistics were too good I have spoken of these 100 cases before, and also shown, that electrolysis is not a dilatation, on the contrary, that when dilatation and even pressure will not pass a stricture, the electrolysis will by its chemical action

Why was it advisable to use gradually larger and larger electrodes? This is a question by a gentleman, who wants thereby to prove that the enlargement of the calibre was done by pressure The answer is, that the electricity can do only a certain work in a certain time, and that it would be impossible to subject the patient to such increased work, and to such prolongated time in one *seance*, without doing great harm You may ask just as well, why do you eat 3 meals a day, and why don't you eat once a week, by taking 21 meals at once It is considered a good result to enlarge the calibre of the urethra by 3 sizes in one *séance*, and when such 3 size larger sound can not be pressed through a stricture, but yields to the action of electrolysis, while no pressure is used, it is the best proof that the electrolysis did such work and not a dilatation This I have often demonstrated Besides, how can the intelligent interrogator expect that a stricture which will only admit a No 9 sound, can be taken grip at by a large bulb like No 28? Such a large

bulb acting as the negative pole could only enter the healthy part of the urethra with its tip, act there on healthy tissue, which would do more harm, and do no good to improve the diseased part No, we want a size for the electrode, which with its tip reaches the beginning of the stricture, engages itself therein, and enlarges by means of its chemical action the calibre by degrees until it is large enough, that the electrode will pass such stricture, making it 3 sizes greater than before the operation According to the nature of the stricture, a 2 to 4 sizes larger electrode, French scale, may be used for one *seance*, and such must be considered a very good result Another eminent gentlemen finds fault, that no endoscope has been used, and that American writers have not given enough details with regard to the size, nature and position of the stricture He also described 1 case of his own as a failure No wonder he failed, because he in reality practiced electro puncture and not electrolysis, and a contraction naturally followed Neither are his objections justified, as I have in my tabular statistics, as well as in other reports of cases, always stated details, as patients' first visit, cause, duration, complication, nature, number, size and seat of stricture, etc I also have used the endoscope for 20 years, and made use of it in the treatment of strictures, when it was indicated, to gain further information I have still to hear of a valid real objection—but on the contrary can state decided advantages of the electrolysis, without wishing to enter into the merits of other methods

THE ADVANTAGES OF ELECTROLYSIS

1 Electrolysis is applicable to all strictures in any part of the urethra

2 Electrolysis will pass and enlarge any stricture, when other instruments or the skill of surgeons fail, which I have often demonstrated

3 It causes no pain or inconvenience

4 It is devoid of danger

5 It is not followed by hæmorrhage, fever, or any other unpleasant consequences

6 It relieves at once

7 The patient is not detained from attending his daily work or business, and can earn his living while under treatment without restraint

8 No relapse takes place

(To be concluded)

SYMPATHETIC OPHTHALMIA CASES IN PRACTICE

Read before the Chicago Medical Society, January 17, 1887

BY W FRANKLIN COLLMAN M D, M R C S, ENG
PROFESSOR EYE AND EAR DISEASES, CHICAGO POLICLINIC

The terrible affliction blindness is so frequently caused by an injury to the eye, which results in the destruction of its fellow, and the treatment of the injured organ places so great a responsibility upon the physician that the introduction of the subject, "Sympathetic Ophthalmia," for our mutual discussion and profit, needs no apology Several evenings and an audience could easily be exhausted in justice to the theme, but regard for yourselves and time compels a very imperfect sketch While some authors use the term *Sympathetic Ophthalmia* synonymously with Sympathetic Ophthalmitis, others use it generically to include "Sympathetic Irritation" and "Sympathetic Inflammation"

These affections are induced in the sympathizing eye by some organic lesion of its companion In the vast majority of cases the lesion in the exciting eye is an inflammation of the ciliary body and the cause of the cyclitis is usually a wound in the ciliary region—which is known as the "dangerous zone" This corresponds to a belt of the sclera 2 lines in width surrounding the cornea, and is the region from which most of the sympathetic affections of the second eye proceed Operative injuries of the ciliary body (such as von Graefe's linear extraction of cataract) are prone to give rise to sympathetic disease Becker, in 1875, collected 22 cases of sympathetic ophthalmia resulting from cataract extraction 15 followed the von Graefe operation and 19 the flap While the above illustrates the danger of the linear operation, the vast number of such extractions not followed by sympathetic disease, shows that simple, uncomplicated incision of the ciliary body is not apt to endanger the second eye It is generally held that acute purulent ophthalmitis is rarely if ever followed by sympathetic disease, yet there are exceptional cases to the contrary reported, and Alt found that of 110 eyes enucleated on account of exciting sympathy, 19 per cent had suffered from ophthalmitis Among other most frequent causes of sympathetic disease are a foreign body lodged in one eye, and the degeneration of a lost eye This is eminently dangerous, if painful or tender in the ciliary region

Sympathetic irritation of the eye is marked by certain *functional* disturbances, among which weakness of the accommodation is a very prominent and early symptom, the patient soon experiencing fatigue and pain in reading, and being disposed to hold the book at a distance The eye is sensitive to light, and readily weeps when exposed to a bright light or the strain of near work Vision may be normal, is occasionally impaired and sometimes there are temporary sensations of darkness In some cases there are neuralgic pains in the eye, and photopsies

Donders describes a sympathetic neurosis denoted by intense photophobia, lachrymation, and spasm of the lids This form of irritation, he thinks, never passes over into sympathetic inflammation Whether the usual form of sympathetic irritation is a condition, *sui generis*, or is a premonitory step of inflammation, is an open question The symptoms of irritation may exist for weeks, months, or years, and then subside or be followed by inflammation

Some authors maintain that sympathetic inflammation is always preceded by symptoms of irritation, the majority perhaps assert that inflammation may occur without such warning In my own experience symptoms of irritation have always preceded sympathetic inflammation, but the warning has often been unnoticed or little heeded by the patient In practice it would be disastrous to act as if an eye with

sympathetic irritation were not in imminent danger, or as if sympathetic inflammation could not occur without warning

Though any structure of the eye may be attacked by sympathetic inflammation, the disease most frequently and in the severest form appears as an iritis or irido cyclitis It often sets in in the less severe form of serous iritis, or as a plastic iritis, and if long continued (as it almost invariably is) extends to the ciliary body and the choroid, produces degeneration of the iris with total adhesion to the lens capsule, and wasting of the eyeball

Next to the lesions of the uveal tract those of the retina and optic nerve are the most important The route or manner by which inflammation of one eye is transmitted to the other is still only surmised McKenzie, in 1844, supposed three possible paths 1 The inflamed vessels of the injured eye communicates a disposition to similar disease to the vessels on the opposite side with which they anastomose in the cranial cavity 2 Irritation is conveyed along the ciliary nerves to the brain and reflected to the corresponding nerves of the opposite side 3 The retina is probably inflamed, and the union of the optic nerves is the chief medium by which sympathetic inflammation is produced

In 1862, Pagenstecher opposed the participation of the optic nerves, and referred the transmission exclusively to the ciliary nerves This view has since been generally held Recently Alt supports McKenzie's view, that the optic nerve plays the chief part in the transmission, and supports his opinion by the result of microscopical examination of injured eyes, in which 90 per cent had affections of the optic nerve and retina

Lastly, Snellen announces that septic bacteria have invaded the sheath of the optic nerve, and believes they are concerned in the production of sympathetic ophthalmia

The time which may elapse between an injury of an eye and sympathy of its companion varies from a few days to the limit only of a lifetime Matts reports a case in which within four days and without premonitory symptoms, an eye was attacked by sympathetic irido-cyclitis, and vision reduced to $\frac{1}{10}$ With the rarest exception, there is no danger of serious sympathy within the first week after injury There is seldom danger in less than three weeks, and as a rule it is at its height in four to six weeks

Before considering the indications for enucleation I will cite three cases somewhat in detail

Case 1 —Bessie R , aged 23, had phlyctenular ulceration of the left cornea, appearing once in about three months I found the cornea bulging, also sclero choroidal staphyloma, and the eye blind The fellow eye had not sympathized Vision was normal with a glass of + 8 D Advised patient to read with a glass + 6 D , to watch both eyes carefully and if either should give the slightest trouble to have the lost eye removed at once The unfortunate girl returned in seven and a half months, saying the sight of her good eye had been failing for five months There was a little pain in the eye when the sight began to fail and twice since Vision was now reduced to counting fingers within two feet The eye externally appeared normal The lost eye has not been the least painful, but upon pressure is slightly tender The exciting eye was removed Two weeks after enucleation the patient could read type of 14 Jæger Soon after this the sight began to fail, and in six weeks the eye was practically blind, being able to distinguish light only There is now atrophy of the optic disc

Case 2 —Mary McD , 3 years of age, fell and struck the left eye on the stump of a tree Severe pain in the eye followed for two to three days, and slight pain for two weeks longer Four weeks after the injury, I find a staphyloma of the superior quarter of the cornea, the tension of the eye reduced to —1, there is no perception of light No spontaneous pain or tenderness of the eye I cautioned the child's mother to watch carefully for any symptoms of irritation in the fellow eye, and if any should appear to return immediately to have the injured eye removed to prevent blindness of the other Seventeen days later the mother returned with the child and reported that *three* days after the consultation there was a little pain and redness of the good eye two to three times in the evening Two days after that the eye became so sensitive to light that the child could not open it Then the eye improved, and in three days seemed well In two days more the eye began to get red, and soon afterwards light began to hurt both eyes Upon examination the injured eye is found quiet The second eye presents general conjunctival hyperæmia, the iris is dull and dilates very slightly but regularly after atropin (grs iv ad ℥j) four times in an hour Sympathetic iritis Enucleation advised as the safest, or a trial of optico ciliary neurotomy The mother refuses the former but consents to the latter

The internal rectus and the optic nerve are divided, the posterior part of the globe turned forward, and the ciliary nerves with all connective tissues dissected from the posterior third of the sclera Two sutures inserted over internal rectus Bandage to eye for three hours, followed by iced compresses Dark shade, and atropin to the fellow eye and ℥ss ung hydrarg daily in the axilla. Five days after operation the eye is slightly prominent and there is $\frac{1}{12}$ inch of hypopion The sympathizing eye is improving Less photophobia and iris clearer

July 1 —Two and a half weeks after operation the second eye is still improving As the mother is compelled to return home soon it is considered safer to enucleate the lost eye, and the operation is performed Three weeks after there is slight haziness of the cornea of the second eye, and photophobia Vision is sufficient to enable the child to get about readily, though it is much impaired

Case 3 —A M , aged 23, farmer, states that he lost the right eye from disease fourteen years ago Since the loss of sight the eye has never been painful At present the ball is one-half normal size There is slight ciliary tenderness, and most probably ossification of the choroid Four years after the loss of the R E the sight of the left began to fail, unaccompanied by any pain Six weeks before consulting

me, the patient being able to distinguish *light only* with the sympathizing eye, had an operation for artificial pupil performed at the Massachusetts Eye Infirmary, Boston The surgeon said the closed pupil was caused by sympathetic inflammation Unfortunately, the operation did not improve vision In a letter replying to a friend of the patient, the operator wrote, "There is no chance of helping Mr M There is nothing more we should advise The operation (artificial pupil) was done as a last resort"

I found the globe of the sympathetic eye of normal size, the tension normal, an opaque lens, a small artificial pupil inferiorly The flame of a lamp could be seen in a dark room at 60 feet Field of vision good As the patient was practically blind, had little to lose by an operation, and possessed so good light perception and field, I decided (in spite of the usual hopelessness in such cases) to operate, and extracted the lens by the lower sections A month later the patient with a + 3½ inch lens could count fingers at 6 feet and had sufficient sight restored to do farm work The stump of the exciting eye was excised It contained a nodule of ossified choroid

Allow me to group together some of the more important points in 28 of the cases that have come under my care Four occurred in children from 3 to 11 years of age 24 in adults from 21 to 67

RESULT OF TREATMENT

Enucleation of the First Eye —Sympathetic inflammation and blindness second eye (2) No improvement

Sympathetic inflammation V = $\frac{1}{15}$ second eye (1) Result, V = $\frac{1}{5}$

Hyperæmia of disc V = 1 J 8 in second eye (1) Result, V = 1 J 12 inches

Sympathetic irritation V = $\frac{20}{100}$ (1) Result, V = $\frac{20}{50}$

Enucleation First Eye and Cataract Extraction Second Eye —Sympathetic iritis and cataract V = Light 1 After operation vision sufficient to find way about the house

Optico Ciliary Neurotomy followed by Enucleation First Eye —Age 3 years Sympathetic iritis and vision sufficient to find her way with difficulty about the house After operation vision considerably improved

Preventive Evisceration of First Eye, Normal Second Eye 3 Cases —No symptoms followed

Preventive Enucleation First Eye Sympathetic Irritation with Normal Vision Second Eye 5 Cases —As is the result almost without exception, all symptoms of irritation ceased

Enucleation of the first eye was objected to by the patient in 9 cases of sympathetic irritation, 1 of inflammation, and 2 in which the second eye was still normal

Upon examination of the enucleated eyes ossification of the choroid was found in 5, a spicula of iron in 1, and in 1 case the ball was twice perforated, and the iron found on the inner posterior wall of the orbit

In regard to the most vital part of our subject—treatment—we will consider only the indications and contra indications for enucleation of an eye which may excite or has excited sympathetic disease in the second eye Augustus Pritchard, of Bristol, England, was the first to enucleate a human eye for sympathetic ophthalmia, in 1851 Von Graefe remarked about 1858 "I only mention this operation (enucleation to ward off sympathetic ophthalmia) as I hear it is performed by some English oculists" Critchett, of London, was the first to point out that enucleation, to be satisfactory, must be resorted to before sympathetic inflammation has set in

The indications for enucleation must have regard to the condition of both eyes, and the question of immediate operation will often depend upon the intelligence of the patient and his opportunity for consulting a surgeon

I will suppose, three conditions of the first or exciting eye

1 Blindness,

2 More or less vision,

3 Acute ophthalmitis,
and three conditions of the second eye
1 Normal,
2 Sympathetic irritation,
3 Sympathetic inflammation,
and will consider each condition of the first eye accompanied by one of the three conditions of the second

1 In case the first eye is blind while the second is still normal, surgeons differ in practice I would strongly urge enucleation to the unintelligent and to children, who do not observe symptoms of sympathetic irritation So many oculists agree that sympathetic inflammation may set in without the warning of irritation, that although this is contrary to my own experience, I would not take the responsibility of not advising enucleation even to the most intelligent and favored

2 In case the first eye has some vision or the possibility of it, and the second is still normal, there would probably be among surgeons little dissent from the advice not to enucleate

3 In case the first eye is acutely inflamed or is suffering from ophthalmitis, and the second eye normal, for myself, I shall never again enucleate an eye if acute ophthalmitis is present, one patient on whom I operated having died four days after from meningitis

4 If the first eye is blind and the second is in a stage of sympathetic irritation, there is no question of the urgent necessity of enucleation to so certainly avoid the terrible risk of loss of the second eye

5 If the first eye possesses vision, and the second is suffering from irritation, it seems to me better to sacrifice a damaged eye with uncertain prospect, than to take the great risk of losing a sound one

6 If the first eye is suffering from ophthalmitis and the second from irritation, I would prefer to puncture and apply fomentations to the first eye till acute symptoms passed—then enucleate, or if an operation be immediately very urgent, I would consider evisceration of the sclera safer than enucleation

7 If the first eye is blind, and sympathetic inflammation is present in the second eye, there is a concensus of opinion that the prognosis in severe cases is most unfavorable, and the instances of recovery are very rare under any treatment The authors I have at hand advise enucleation—some very strongly—some without having seen any benefit, others having seen benefit, while none suggest any harm to second eye from the operation The authors are Nettleship, Lawson, Wolfe, Williams, Noyes, De Wecker, Mittendorf, Juler, Carter, Stellwag, Wells, Schweigger and Mayer On the other hand, so good an authority as Mauthuer strongly advises against enucleation when serous iritis or plastic iritis only is present in second eye He says "In my opinion, there cannot be the least doubt that iritis serosa may be transformed into iritis maligna by enucleating the other eye, and we observe cases in which there is no doubt that plastic iritis, if left to itself, would have passed off as a mild attack, whereas the enucleation excited it to irido-cyclitis" Mauthuer supports his view by citing three cases—one each by Mooren, Haskett Derby and Knapp, in which serous iritis after enucleation developed respectively into irido cyclitis, repeated attacks of iritis, and irido choroiditis, with destruction of the eye, also one case of Samelsohn's in which sympathetic serous iritis recovered without enucleation The argument does not seem to me strong

In Mooren's case, after enucleation of the first eye the irido-cyclitis followed on *iridectomy* in a sympathetic eye, a very frequent result In Derby's and Knapp's cases enucleation was followed by great improvement, then relapse Is it not reasonable to say the results followed in spite of enucleation?

I cannot conceive it other than damaging to the second eye not to remove the *exciting cause* of the inflammation Again, if enucleation acts as an exciting cause of inflammation, why does the operation so invariably dispel irritation? With the histories of improvement in my own four cases, and in those of other operators, I would remove the first eye

8 If the first eye has some vision, and the second sympathetic inflammation, enucleation should not be performed The patient has a chance of vision with either eye, while an operation would lose one eye and be of doubtful benefit to the other

9 With ophthalmitis of first eye, and sympathetic inflammation of second eye, first treat the ophthalmitis and then enucleate

Those who object to having an eye removed to avoid sympathetic disease (even though, as is usual, it be a sightless blemish and a most dangerous companion), might take advantage of the optico ciliary neurotomy This operation, though less protective than enucleation, deserves more frequent trial

The advantages of evisceration over enucleation, in the greater safety to life (as I think is fairly urged), and the greater size and mobility of the stump for an artificial eye, deserve more consideration than they receive As a full report would be too lengthy, I will epitomize the remainder of 28 of the cases that have come under my care

Case 1 —Aged 40 The patient, seven months before consulting me, scratched his eye upon the limb of a tree When examined the eye was blind and presented a corneal staphyloma and cyclitis The fellow eye was normal Preventive evisceration was performed, which was followed by more reaction than usually occurs after an enucleation of the bulb

Case 2 —Aged 30 A piece of iron entered the eye Upon examination three hours later vision was only equal to perception of light The iris prolapsed through a sclero-corneal wound The prolapsed iris was excised, cocaine and cold applied to the eyes The patient would not consent to evisceration Two days later a search for the piece of steel in the eye was unsuccessfully made with a Gruening's magnet, after which the eye was eviscerated The steel was found in the vitreous mass A year later the stump moved an artificial eye much more extensively than is usual after an enucleation, and the upper lid is much less shrunken

Case 3 —Aged 44 A blow (from a stick) on the eye the previous day produced a sclero corneal

wound, and blindness and incipient ophthalmitis Preventive exenteration of bulb was performed

Case 4 —Aged 44 The eye was struck by a twig A tender stump ¼ the size of normal eye remained Enucleation was advised, but not consented to

Case 5 —Aged 10 The eye was struck by a stone Four years subsequently the eye was found blind There was a scleral cicatrix, a closed pupil and cyclitis The fellow eye appeared normal, but vision was reduced to ½ Enucleation of first eye performed, and seven months after the vision of the second eye had doubled

Case 6 —Aged 53 At the age of 16 the eye was struck by a stone A sclero choroidal staphyloma presented, and the eye was blind The second eye was sensitive to light and tender, vision normal Enucleation of the lost eye

Case 7 —Aged 38 Twenty five years previous to consultation the eye was struck by a piece of exploded boiler There is ossification of the choroid, the eye is blind Vision of fellow eye $\frac{20}{20}$, but the eye is easily fatigued in reading (asthenopia) Enucleation of lost eye was soon followed by recovery of the sympathizing eye The vitreous of the enucleated eye was replaced by bone

Case 8 —Aged 49 Eye lost twelve years previous to consultation, from a blow of a bone The lost eye presents an ossification of the choroid, and suffers from cyclitis There is sympathetic irritation of the fellow eye The lost eye was enucleated, and two weeks later the symptoms of irritation of second eye had nearly disappeared The vitreous of the enucleated eye was found nearly replaced by bone

Case 9 —Mr J , aged 45, was injured by a piece of iron from a hammer which flew some forty feet and entered the right eye Four hours after the injury I found a wound through the lower lid, through which the metal had passed and entered the eye below the lower cul de sac, hæmorrhage in the vitreous, some reaction and light perception only One week later there was pretty severe ophthalmitis of the injured eye, and sympathetic irritation and reduced vision of the second eye Enucleation was performed, and followed by rapid recovery of the sympathetic eye The chip of metal was found upon the inner wall of the orbit near the optic foramen, having twice perforated the eyeball

Case 10 —Aged 45 A piece of steel is supposed to have entered the eye fifteen years previous to consultation The second eye remained quiet for six years after the injury Since then there has been severe pain in the first eye and the second has been very sensitive to light, watered much, and has been unable to read long at a time (accommodative asthenopia) *Present state* First eye very painful, cyclitis, cataract *Second eye* Vision = $\frac{20}{20}$, asthenopia, lachrymation, photophobia Enucleation advised, but objected to

Case 11 —Aged 23 Eight years since a piece of steel flew from a hammer and struck the eye The injured eye presents cyclitis, detached and pigmented retina In second eye vision = $\frac{20}{20}$, lachrymation, photophobia Enucleation advised

Case 12 —Aged 36 Eye lost from disease four years before consultation Cyclitis and anterior staphyloma of lost eye, which has been painful at times since injury Second eye weak and painful when the first eye suffers Enucleation objected to

Case 13 —Aged 23 Eye destroyed in infancy from prick of a pin Twenty three years later the lost eye shows cyclitis and corneo scleral staphyloma Second eye has periods of conjunctival injection and photophobia Vision = $\frac{20}{20}$ Enucleation refused

Case 14 —Aged 36 Six years since an ulcer perforated the cornea There is leucoma adherens, bulb ⅔ size of normal Second eye Vision = ½, lachrymation, photophobia, and weakness of accommodation Enucleation objected to

Case 15 —Aged 21 One eye has been blind from infancy It has given no trouble till four years ago, since when it has been painful, and the fellow eye has been weak and watery First eye Cyclytis, closed pupil, cataract Tension — 2, globe ⅔ Second eye Vision with + 42 cyl = ¾, lachrymation, accommodative asthenopia Enucleation objected to

Case 16 —Aged 55 One eye has been blind for forty years During the past five years only it has at times been painful It presents atrophy of cornea, tremulous iris, cyclitis The second eye is painful when there is pain in the lost eye Enucleation objected to

Case 17 —Aged 11 At 4 years of age lost one eye from "inflammation " Six and one-half years later there is cyclitis and a shrunken bulb The second eye at times is injected, painful and sensitive to light Optico ciliary neurotomy or enucleation advised Refused Eighteen months later, the symptoms of sympathetic irritation were much less marked

Case 18 —Aged 11 A "growth" destroyed one eye at the age of 3 months When examined the small stump was found exceedingly painful on pressure It had been excruciatingly painful for six weeks, and there was sympathetic irritation of the second eye All pain of stump and the sympathetic irritation ceased four days after enucleation

Case 19 —Aged 35 Patient presented himself four weeks after a blow on the eye by a knife handle Present state Sclero corneal wound, blood in anterior chamber, cyclitis Vision equal to light perception Second eye Photophobia, pain on reading a few minutes V = $\frac{20}{20}$ Enucleation was refused ℞ Fomentations to injured eye, and leeches to the temple Four weeks later A dislocated lens is now visible Less pain in the eye Vision equal to seeing lamplight at 8 feet Enucleation again urged, objected to ℞ Fomentations and atropine Five weeks later the patient writes "My well eye has not been able to see print during two and a half weeks, and the eye is red " I replied "The eye may be completely lost if the injured eye is not immediately removed " The patient was not further heard from

Case 20 —Aged 40 Five years since the patient lost an eye by burn of lime It is occasionally painful The fellow eye is blind from sympathetic keratitis ℞ Enucleation Ossification of choroid

(bone ¼ size of a pea) of enucleated eye No improvement in vision 4½ months later

Case 21 —Aged 67 A Graefe's scleral linear section for the extraction of a cataract resulted in a plastic irido cyclitis and keratitis of the operated eye Four months later the second eye suffered from sympathetic irido cyclitis A year later still an extraction of cataract, followed by an iridectomy, and again an iridectomy of the second eye, did not restore any vision The patient had refused to have the eye first operated on enucleated

Case 22 —Aged 4 Eye struck by an axe When examined the eye was blind, and showed a depressed corneo-scleral cicatrix The second eye was suffering from sympathetic iritis and cataract, with sufficient vision to enable the child to find his way about the house Enucleation of first eye, followed later by extraction of the cataract, and subsequently by an iridectomy, resulted in some improvement in vision

Case 24 —Aged 29 At 4 years of age the eye was punctured by scissors The lost eye presented a corneal and sclero choroidal staphyloma The fellow eye had vision equal to reading No 1 Jæger type very slowly at 8 inches The whole optic papilla was hyperæmic The lost eye was enucleated, and one week later vision rose to reading No 1 Jæeger fluently at 12 inches, and the optic disc showed hyperæmia only at its periphery

Case 25 —Aged 34 Lost right eye in infancy from disease During fifteen years previous to consultation the second eye has been at times painful and red, and vision not perfect There is cyclitis of the atrophied globe of the exciting eye The sympathetic eye has vision equal to $\frac{20}{60}$ and equal to 2 Jæger 6 inches Pigment dots on lens capsule from past iritis, floating bodies in the vitreous and optic neuritis Seven weeks after enucleation the patient wrote "Vision has much improved and the eye is strong" A bony mass one-half the size of a marble was found in the choroid of the enucleated eye

DYSTOCIA FROM SHORT OR COILED FUNIS, AND ITS TREATMENT

Read before the Medical Society of the District of Columbia, April 27, 1887

BY A F A KING, M D,
OF WASHINGTON, D C

In a paper read before this Society six years ago, and published in the *American Journal of Obstetrics* (New York, vol xiv, No 2, April, 1881, pp 322–328), and in a subsequent publication in the *Transactions of the American Gynæcological Society* for 1886, I have called attention to protracted labor due to short or coiled funis, and laid some stress upon the method of expediting delivery in such cases by changing the posture of the lying-in woman from a recumbent position to a sitting, kneeling or squatting one An instinctive desire on the part of the woman to assume such a change of posture was also mentioned as one of the symptoms indicating shortness or coiling of the cord when it impedes delivery

At the time of reading my first paper, six years ago, I hopefully requested the members of this Society to take the matter into consideration and report the results of their observations in practice, bearing upon the questions I had presented I regret to say that, thus far, no member of the Society has reported any case relating to this subject, with the exception of Dr W H Taylor, who kindly sent me notes of one case, which I incorporated in my recent paper published in the *Transactions of the American Gynæcological Society*, and which, in all respects, illustrated the views I had previously presented Neither have any cases conflicting with these views (and which would have been equally useful and acceptable) been reported It can scarcely be doubted that some cases, at least, of protracted labor from short or coiled funis, must have occurred within the experience of the members of this Society during the last six years They have therefore, it would seem, either been overlooked, owing, perhaps, to the absence of any *serious* danger attending them, or else I have failed to present the matter in such a way as to secure for it the earnest consideration which I am more and more convinced it deserves Hence, I again solicit the attention of the Society to this subject

The cases in which a short or coiled cord leads to any serious danger are, perhaps, few, they nevertheless occasionally occur, as the records of obstetrical literature amply demonstrate But there are, I believe, very many cases in which, without any serious danger, labor is considerably protracted and many hours of agony added to the parturient woman's sufferings, and which might be safely and quickly ended by the postural treatment to which I have referred It is to this latter class of cases that I have particularly invited attention That a woman should be permitted to suffer, unnecessarily, a single hour—much less several hours—when such suffering can be safely avoided, is intrinsically wrong And while moderate protraction of a labor is not necessarily serious, yet, other things being equal, it may be said that every hour of delay, produced by accidental complications, does add *something* to the element of danger, especially with women whose nervous energies have been from some cause enfeebled, and who, in passing through the ordeal of childbirth, have no surplus strength to spare for complicating accidents, and consequent protracted suffering Furthermore, when a protracted second stage of labor, from unsuspected short or coiled cord, leads to the application of forceps (a not uncommon occurrence), with, especially in primiparæ, rupture of the perineum, the element of danger is again, to some extent, increased

What I desire, in particular, to insist upon is, that the danger in these cases (whatever its degree), the delay (whatever its duration), and the suffering (whatever its intensity and persistence), may be obviated, in the great majority of cases—perhaps not in all—by changing the posture of the female as already stated

While of late, modern obstetric authors, for the

most part, ignore coiling of the cord as a cause of dystocia, it is not a matter of surprise that they say but little of its treatment, and nothing whatever of its treatment by posture There was a time, however, in the history of obstetrics, a century or two back, when protracted labor from short cord was recognized and treated of by the then leading authorities of the obstetric art And among the methods of treatment then employed, I find—with considerable gratification—that the best results were obtained by changing the posture of the woman exactly in the manner that I have recently recommended And one of the chief objects in this paper is to reinforce my position with the recorded experience of those who have successfully adopted the method of treatment referred to, and I may also mention another method advised by Smellie, with which, however, I have had no practical experience

But before citing these older authorities, it may be of interest to inquire why the orthodox teaching of modern ones has so materially changed as that but little mention is now made, in our latest text books, of this kind of dystocia? I cannot but think the explanation of this change of opinion must be referred to the more general and frequent use of forceps in protracted labor during the last century That is to say given a case in which the head has reached the perineum, or has almost reached it, and then becomes arrested, or fails to make material progress, and in which, after several hours of ineffectual effort, the woman begins to exhibit signs of commencing exhaustion under these circumstances, nine times out of ten, the modern obstetrician—having simply satisfied himself that there exists no malproportion between the head and pelvis, and that there is no fault in the mechanism—will apply forceps and forcibly extract the child, never suspecting a short or coiled cord until he finds it after the head is born In the great majority of cases this method of practice succeeds without material injury The cord is not ruptured, the uterus is not inverted, there may, perhaps, be more bleeding than usual, owing to the placenta having been prematurely separated from the uterine wall by traction on the cord, before the child was expelled But by the usual pressure of the hand upon the fundus uteri during the delivery, the womb contracts, the placenta is found in the vagina, or partly in it, projecting from the os uteri, the case ends well, mother and child recover, and thus the delay occasioned by the coiled or short cord is disregarded and considered to be of no material importance, the little difficulty being so easily overcome by the use of forceps This is modern practice But it was different a century ago, when the use of "instruments" in labor was much less frequent, and regarded with something like dread or even timidity Dr Davis, of London, an eminent practitioner and teacher of midwifery, himself the inventor of an improved forceps bearing his name, we are told, only applied the instrument with a frequency of once in about 1,200 deliveries, while the city practitioner of to day, not uncommonly, applies forceps as often as once in every 6 or 7 labors Moreover, of late years the modern obstetrician has become disenthralled from the maxim of Dewees—"meddlesome midwifery is bad"—which formerly exerted an exaggerated influence and led to injudicious expectancy in obstetric practice

These, I think, are the real reasons why shortness of the cord, as a cause of dystocia, has been ignored—at least more or less ignored—by recent obstetrical authorities That labor is protracted by the complication in question, is just as true now as it was a hundred years ago, and our being able in most cases to remedy the difficulty by the unscientific application of "brute force" in violently extracting the fœtus with forceps, should not be allowed to stand in the way of that higher and far more scientific course of action which demands a recognition of the cause of delay, and thus opens the door to other and more desirable methods of treatment, one of which, I am persuaded, is change of posture I have said forceps overcome the difficulty in a great many cases In others, however, forceps completely fail to accomplish delivery, the force required being either beyond the strength of the obstetrician, or exceeding the limit which he considers to be judicious in obstetric practice Who of us cannot recall cases having something like the following history? It is an ordinary labor case, the head is at the perineum, there has been no progress for several hours, there are symptoms of exhaustion Dr Tommas puts on the forceps, pulls as hard as he dare, tires himself out, and gives it up as a bad job Dr Richard is sent for, and does exactly the same Then Dr Henry comes and performs the same programme for the third time, and with the same result Eventually, during the second round, or perhaps during the third, one of them succeeds in extracting the head, and an unsuspected short or coiled cord is discovered, which may or may not be regarded as a cause of the difficulty—usually *not*, in modern practice If the child be alive, the obstetricians are credited with wonderful skill, if it be dead, no one is surprised after considering the long and difficult instrumental delivery which required "three doctors" Indeed, no one would wonder if the woman died, and if she survive, what dangers, of bruising and laceration of the soft parts, of nervous shock, of subsequent acute inflammation, fever, and septicæmia, and what agonies of pain, has she not endured, from these prolonged and violent efforts, at the hands of Drs Tom, Dick and Harry!

It may be said this is an exaggerated picture I acknowledge it represents a minority case I have already said forceps will *do*, in the majority But between the *very* difficult, and *very* easy cases, there are many intermediate ones of moderate danger and moderate difficulty It may be further supposed that no such case would occur in the hands of a careful and intelligent obstetrician He would, we should think, suspect the coiled cord before birth, diagnosticate it, and institute treatment accordingly Yet why should he do this when the leading authorities of the period, whose teachings he has been taught to follow, give no attention to coiled cord as a cause of dystocia, but, on the contrary, ignore or deny it

To illustrate that cases of the greatest gravity may

occur occasionally, even to the most expert practitioners, I may call attention to a case reported to the Obstetrical Society of New York, about a year after the publication of my first paper, by Dr W T Lusk (see "Supplement" to the *Am Jour of Obst*, N Y, November, 1882, pp 324–326) He tells us "A patient was brought to the Emergency Hospital, who stated that she had been in labor five days Before her admission a number of physicians had seen her, and had made ineffectual attempts at delivery" (He does not say that these "attempts" were made *by forceps*, but I presume they were It is the same old story) When Dr Lusk first saw her, the external organs were acutely inflamed, temperature 103 5° The head could be seen through the vulva, close down by the outlet The house physician had delayed sending for Dr Lusk for some *six hours*, because it appeared as if the child would be born every moment Dr Lusk gave ether, applied forceps, but found much more resistance in delivery than he had expected In a short time, however, he managed to extract the head, and then on passing his finger up, found the cord very tense, and wound a number of times round the neck "He was about to cut the cord, which *evidently had been the cause of delay in delivery*, when a pain came on, and the child, placenta, and cord were expelled together" He adds "The child, *of course*, was dead" And a further interesting addition to this history was the death of the mother a few days later, from sloughing of the vagina communicating with the peritoneal cavity It is further stated that "the slough doubtless occurred as the result of the great and long-continued pressure of the child's head The case was specially interesting regarding the difficulty of labor due to shortening of the cord, a question exciting considerable discussion of late"

In the report of the discussion of this case, Dr Barker is credited with the following remarks "Regarding shortness of the cord as sometimes being a cause of difficult labor, he considered it an established fact, and he himself had often seen examples of it A case which he had reported before might again be alluded to When labor came on he found no disproportion between the size of the fœtal head and that of the pelvis The presentation was favorable and the labor pains were regular and vigorous, finally the head came down and began to distend the vulva, but afterwards the patient had severe pains for about an hour, without the slightest progress being made Chloroform was given, and the forceps applied, but just before extracting the head he withdrew the instrument" (the report does not state *why* he did so, but I suppose it was because the head would not come) "passed up his finger, and found the cord wound three times round the neck, and very tense Having no bistoury with which to divide the cord, he sent hurriedly to a neighboring physician for one, which arrived soon enough to enable him to extract the child alive, after division of the cord It was perfectly evident that the short cord had retarded labor, and, had he proceeded with delivery by the forceps, the placenta must have come away, and in all probability, the child's life, and perhaps the mother's, been destroyed The cord was 11 inches long, or but 2 after allowing three circles round the neck This was about twenty years ago, before then he was always in the habit, before bringing down the head, of passing in the finger to see whether the cord was round the neck, and if so, cutting it, which he had found it necessary to do on several occasions, he was more particular to do so since, and was convinced that this was oftener a cause of difficult delivery or retarded labor, of death to the child, and of violent hæmmorrhage before the expulsion of the placenta, than was *commonly supposed*"

In considering what we here find in this report, I think we may fairly conclude that neither Dr Lusk nor the several physicians who had made ineffectual attempts to deliver, had suspected the real cause of delay before the instruments were applied And in Dr Barker's case it would seem, the same thing occurred, for he did not feel for the coiled funis until removing the forceps just before the head was extracted If then mistakes of this sort occur with men so eminent in the profession as Drs Lusk and Barker, they may, and doubtless do occur, with much greater frequency in the practice of others who are less experienced and expert With regard to both these cases I am much inclined to the opinion that delivery would have occurred without the use of instruments—either forceps or bistoury—and probably in a very few minutes, had the women been placed in a sitting posture

In conclusion I may now quote from some of the older authorities, as to the influence of a short cord in retarding labor, and the methods of treatment advised to be practiced

Dr David Spence, writing in 1784 ("A System of Midwifery," Edinburgh, pp 175–178), says "The delivery may be retarded by the natural shortness of the umbilical cord, or its being twisted round the neck, or any other part of the child This is commonly first discovered when the head is so far advanced that every pain seems to promise the delivery of it, but which, on the pain going off, retracts again as far as before We are advised by many authors of note, and among others by Smellie ("Midwifery," vol i, p 188) to introduce in a case of this nature, one or more fingers into the rectum, and during the pain, by pressing upon the forehead of the child at the root of the nose, detain its head till the return of the pain, when it will gradually be pushed further and further down, so as at last it is forced through the external parts" "But I have seen several cases (p 177) where almost one half of the head was, with every pain, protruded through the parts and as often retracted, and *that for so long a time*, as to render either having recourse to the above practice, or relieving the woman by the assistance of forceps, in order to shield her from inflammation of the parts consequent upon the continued pressure of the child's head against her in the birth" Dr Spense does not mention postural treatment

Dr Smellie in his work (vol ii, p 291) reports a case in which the cord was "four times convoluted" and in which delivery was accomplished by the rectal method In another case (pp 292–3) he says "the

head came down to the middle of the pelvis after several hours—the waters broke at the os externum —" the head began to be drawn upwards immediately after the membranes broke " " I resolved to assist in bringing the head lower, and keeping it so, with the help of the forceps, had it continued much longer in that situation, but as she had every now and then a strong pain, I first tried what might be effected by different positions, and directed her to bear the pains standing, sitting, kneeling, lying on one side, or resting on the bed in a posture between sitting and lying This last was the most successful, and in three or four strong pains, the head, though still retracted, advanced lower and lower and began to dilate the os externum But observing that it made another stop I introduced two fingers into the rectum and completed the delivery " The funis was coiled three times around the neck, Dr Smellie here tells us that he found this rectal method in Mr Ould's treatise, published in 1742

Dr Samuel Bard (" Compendium of the Theory and Practice of Midwifery," New York, 1819), after referring to Smellie's rectal method, goes on to say " It is, therefore, more safe to leave this matter to the effect of a little longer time, and a few more pains, turning the woman from her side to her back, and with her head and shoulders so much raised, as to add the weight of the child to the pressure of the pains, or, what may prove more effectual, to get her upright on her feet at the back of a chair, and sometimes, though not apparently for the same reason, kneeling at the bedside will produce the same happy consequences " On page 262 he describes a case in which, however, he does not seem to have employed a change of posture He says " In time of pain the vertex pushed down into the pelvis I gave the patient every encouragement in my power, having reason to believe the event would be speedy and favorable, but herein I was disappointed, for although the pains still continued powerful, they were still ineffectual for many hours, which surprised me the more as the uterus had receded from the head of the child, which was not large, the woman, after having undergone uncommon severity of pain for the last seven hours was finally delivered " The funis was four times convoluted round the neck of the fœtus which came away together with the placenta "

Prof Henry Miller, of Louisville, (" Principles and Practice of Obstetrics," 1858, pp 489–450) writes " It was at one time very generally believed that such a disposition of the cord may operate as a serious impediment to the expulsion of the head, the shortened cord retracting the head upon the subsidence of each pain, and it was even deemed necessary in some instances to divide it with scissors to allow the head to emerge " He then refers to Smellie's rectal manœuvre, but says " there is reason to doubt its realty," and that the efficacy of the alleged pressure was most likely due to the consequent continued pressure upon the resisting perineum, which (and not the short cord) caused recession of the head

Simpson, in his " Lectures on Obstetrics," 2d ed , 1858 p 554, says " In some cases shortness of the funis or twisting of the cord around the fœtus, forms an impediment to labor Naègelé and others have doubted that shortness of the cord can act in this way " " Plenty of cases are on record, however, in which difficult labor occurred in connection with shortness of the funis "

Dr Lee, (" Lectures on Midwifery," p 121,) says " There can be no doubt that it is a very common cause of protracted labor " On the other hand Churchill (p 108) states that coiling of the cord is alleged to be a cause of difficult labor, owing to the shortening occasioned by it, but this he believes "to be wholly imaginary "

Denman, in his " Introduction to the Practice of Midwifery," 1832, 7th ed , London, pp 229–30, remarks that " The shortness of the funis is always to be suspected when the head of the child is retracted upon the declension of the pain, and it may sometimes be discovered that it is more than once twisted round the neck of the child long before it is born It has been thought that far the greater number of children are born with one or more convolutions of the funis round the neck

" Various methods have formerly been recommended for preventing this retraction of the head, some of which are insufficient and others unsafe, and the inconvenience is usually overcome by giving the patient more time But if the child should not be born when we have waited as long as we believe to be proper and consistent with its safety, or that of the parent, it will be *requisite to change her position*, and instead of suffering her to remain in a recumbent one, to take her out of bed, and raise her upright, to permit her to bear her pains in that situation, or, according to the ancient custom of this country, to let her kneel before the bed, and lean forwards upon the edge of it, or, as is now practiced in many places, to set her upon the lap of one of her assistants By any of these methods the retraction of the head of the child is not only prevented by its own gravitation, but the weight of the child will be added to the power of the pain, and it will likewise be expelled upon an inclined plane instead of a level In the course of practice, I can with *infinite satisfaction*, recollect a *great number* of cases, in which, by adverting to the benefits gained by an erect position, labors have not only been accelerated, but the use of instruments, which were before thought necessary, has been avoided "

Without accepting all of Dr Denman's statements, his practice sufficiently indicates that the postural treatment of dystocia from short cord is by no means new, but a method already demonstrated to be useful, although of late years overlooked or neglected

His theoretical explanations of its utility are in part correct, and accord in some degree with my own, as well as with those of Dr Barnes, of London, who in discussing Dr Duncan's late essay before the London Obstetrical Society, (" Trans Obstet Soc of London," vol xxiii, 1881, p 254) said " he would submit, as a means of lessening the tension of the cord artificially shortened, the method of compressing the uterus downward during the second stage " I believe, however, no one can do this half so easily

or effectually by manual pressure, as can be accomplished by changing the posture of the woman in the manner before stated

To illustrate with what indifference coiling of the cord is regarded by the general practitioner, I may call attention to "A Country Doctor's Obstetric Record," recently published in the *Philadelphia Med. and Surg Reporter*, for April 9 and 16, 1887, by Dr G Law, of Greeley, Colorado His record includes about 360 labors While it is true that in many normal cases, very meagre particulars are given, in a good number in which *abnormal* phenomena occurred, they are dwelt upon with considerable detail In *not one* instance does he make any reference whatever to coiling of the cord Yet he does mention several cases (about a dozen) in which a lingering second stage required the use of the forceps and some of them with rupture of perineum With relation to *actual* shortness of the cord, he gives one interesting case, as follows

"Feb 22, 1882 Mrs S, a very large, strong woman Vertex The most forcible expulsion or second stage efforts I ever witnessed, tried to modify them by the free administration of choloroform Notwithstanding the extreme force of the expulsive efforts, and a most capacious pelvis, and no fault of position in the child, the second stage was protracted Finally the child, a large and finely-formed male, together with the placenta and a *pailfull of blood*, was suddenly expelled The child dead and completely exsanguined The cause was a funis 4 inches long, abnormally thick and strong The placenta had been pulled from its uterine attachment before the completion of the labor, and the child had died exsanguined Would I have saved the child if I had used forceps and delivered quickly?"

My answer to the doctor's question would be You might in all probability have saved it by changing the posture of the woman, so as to force the entire womb and its contents deeper down into the pelvic cavity

MEDICAL PROGRESS.

RAPID DILATATION OF THE CERVIX, ETC —In the Section on Gynecology of the IXth International Medical Congress DR W H WATHEN read a paper on this subject He had learned in the field of experience and observation of the bad results obtained in efforts to dilate the cervical canal by tents, or to enlarge or straighten it by incisions to cure dysmenorrhœa and sterility He begged to call attention to the more satisfactory means of rapid dilatation with the bivalve or double-bladed dilators now in use, and especially to the substitution of an instrument of his device for Goodell's modification of Ellinger's dilator If tents were used, he preferred the tupello to any other variety, it being less apt to cause septic inflammation than the sponge, and dilated more rapidly, regularly, and better than the tangle He referred to endometritis, pelvic hæmatocele, pelvic cellular or peritoneal inflammation, septicæmia, pyæmia, and tetanus, as complications accompanying or following the use of tents, and did not believe that any good results, apparently, were permanently obtained He claimed the two bladed dilators are relatively aseptic and are easily used, complete the operation at one sitting, and that the dilation is comparatively free of immediate or subsequent dangers It nearly always cures the dysmenorrhœa, and often removes the causes of sterility He thought the results of the incision of the cervix up to the vaginal junction, or through the internal os, anteriorly, posteriorly, or bilaterally, even more unsatisfactory than those following the use of tents He dilates the cervix in his office, without a local or general anæsthetic, to the extent of half an inch, and allows the woman to walk or ride home a few minutes after In dilatations of from ¾ to 1 inch, he gives a hypodermic of morphia and atropia, then brings the patient under the influence of chloroform before operating He urges great cleanliness, and all means to prevent septic infection He uses three sizes of dilators, the largest the one he devised He explained the points of superiority over Goodell's

In conclusion, he urged that the operation should not be performed if there is any pelvic inflammation or trouble in the tubes or ovaries, and never, in any case, until we are reasonably positive that the cause of the trouble is in the cervical canal

Dr A Martin, of Berlin, said that the dilatation of the uterus as an operation had undergone remarkable changes since its origination The instruments shown by Dr Wathen are an improvement The great object is to open up the internal os The degree of dilatation may be required to be less in some cases of small cervix —*Med Record*, Sept 10

FUNCTION OF THE BLADDER —F BORN has examined the literature of this subject since the time of Haller He presents a careful consideration of closure of the bladder in the dead and living body, sensibility, mobility and electric irritation of the organ, and of the nerves of the bladder The conclusions of special clinical interest drawn are

1 By direct and indirect Faradization and Galvanization we can cause no certain contractions of the bladder

2 The existence of a vesico-spinal centre in the lumbar cord, a centre which regulates closure of the bladder, is not proved and unnecessary in man, since the internal sphincter vesicæ does this by means of a sensitive detrusor centre That name may therefore be given to the detrusor centre in the lumbar cord

3 All acute spinal lesions cause retention, those at the level of the lumbar cord by direct paralysis of the bladder, others by lowering the tone, during which the bladder becomes so distended by urine that it loses its contractile power Under treatment the first condition remains, the latter is improved, and micturition takes place as a reflex act

4 The supposition of reflex controlling fibres, which in micturition control the normal reflex of the spincter urethræ, and lesion of which causes the so-called spastic retention or urine, is unfounded —*Deutsche Zeitschr f Chirurgie*, Bd xxv, S 118

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE $5 00
SINGLE COPIES 10 CENTS

Subscriptions may begin at any time The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters

NINTH INTERNATIONAL MEDICAL CONGRESS

The Ninth International gathering of medical men took place in Washington, Sept 5, and continued its work until the afternoon of the 10th, with a harmony and good fellowship seldom witnessed in so large an assembly on any other occasion In the number of members in attendance, in the number of nationalities represented, and in the quantity and quality of the work done both in the General Sessions and in the Sections, this Congress will compare favorably with any that have preceded it, not even excepting that of London, in 1881 Neither was there any lack of generous hospitality The opening of the Congress by President Cleveland, the Address of Welcome by Secretary Bayard, the Conversazione in the grand Pension Hall, followed by a most elegant banquet given by the American Association of Medical Editors to the editors and representatives of the medical press from other countries, filled out the first day and evening The reception by the President and Mrs Cleveland and the visit to the Corcoran Gallery on Tuesday evening, the lawn party for the ladies by Mrs Dent on Wednesday afternoon, and elegant receptions in the evening by Hon Mr Glover, — Wilson, and Dr A Y P Garnett, the beautiful lawn reception for the ladies accompanying the foreign members of the Congress at Grassland by Secretary Whitney on Thursday afternoon, and the magnificent reception and banquet at Pension Hall in the evening, the free excursion for the foreign members and their ladies, to Mount Vernon on Saturday afternoon, and the grand free excursion starting the same evening for Niagara Falls and returning on the following Tuesday, constituted an exhibition of liberal and elegant hospitality that elicited from the members of the Congress from other countries the warmest commendation, as may be seen by their emphatic expressions in the closing session of the Congress, on the steamer returning from Mount Vernon, and at Niagara But in addition to all these hospitalities admirably superintended by the Committee of Arrangements, elegant lunches were given by the presidents and officers of many of the Sections to the members of their own Section We congratulate all the readers of THE JOURNAL on the full and gratifying success of the Ninth International Medical Congress

THE NATURE AND TREATMENT OF FEVER

The Address of DR AUSTIN FLINT before the International Congress on "Fever its Cause, Mechanism and Rational Treatment," is one of interest to the physiologist, the pathologist and to the general practitioner Its object, as he stated, was to show how the metamorphosis of matter involved in the normal production of animal heat is accomplished, and how the abnormal production of heat in fever, involving, as it does, abnormal activity in the metamorphosis of tissue, may be restricted, and how abnormal destruction of tissue may be limited and repaired Before going further it may be well to give the reader Dr Flint's definition of fever, as in this way he may be able more readily to follow the general discussion of the subject "Fever, as observed in the so called essential fevers, may be defined as a condition of excessive production of heat, involving defective nutrition or inanition, an excessive production and discharge of nitrogenized excrementitious matters and carbonic acid, with waste and degeneration of tissues, and partial or complete suppression of the production and discharge of water "

It is known that the production of animal heat is a phenomenon of the general processes of nutrition, and that the process with which the production of heat is most intimately connected is oxidation of certain materials which are either contained in the food or form part of the body tissues Much time has been expended by physiologists in attempting to ascertain the relations between the consumption of ogygen (with the production of certain excrementitious matters) and the generation of heat within the body, but thus far no accurate method has been arrived at Dalton and Flint have both shown that there is generally an excess of water discharged from the body over that introduced, and it has been shown that a large proportion of the hydrogen (about

85 per cent) introduced in organic combinations with the food, cannot be accounted for by the organic ingredients of the excreta It must seem then that, under certain circumstances, water is formed in the body by the union of the oxygen and hydrogen taken in And, "if it can be assumed that water is formed in this way, the heat-value of hydrogen being very great, there is little difficulty in accounting for the heat which has been estimated by direct observation to be produced in the body, as well as for a considerable surplus of heat expended in the form of muscular force" Now, if it be assumed that water is formed *de novo* in the body, while in its method of production it closely resembles carbonic acid, it differs from it in its uses as regards nutrition it is a solvent, in which it is aided by carbonic acid, the presence of which, especially in the urine, increases the solvent properties of the organic liquids And as regards the tissues, water tends to preserve their proper consistence But the water produced in the body by the union of oxygen and hydrogen behaves, as regards its production and elimination, like an excrementitious matter If we accept these propositions it must be clear that water and carbonic acid are the two excrementitious principles with whose production animal heat is most closely connected Under ordinary circumstances of alimentation, says Dr Flint, the production of carbonic acid probably has the greater relative importance, but in starvation, while the excretion of carbonic acid is diminished, the production of water is probably very largely increased, and it is evident that the production of carbonic acid is a much more important factor in the generation of animal heat than is the formation of urea.

Bacteriological studies have made it probable that all the essential fevers are primarily due to the presence of microorganisms In discussing the mechanism of fever Dr Flint considers as the type of fever the pyrexia of typhoid fever, produced by a definite microorganism and having a duration restricted within certain limits which do not vary widely Symptomatic fevers and the question of pyrexia due to exposure to external heat are not considered in this Address The cause of typhoid pyrexia may be regarded as twofold, the more important factor being an exaggeration of the chemical changes taking place in the organism, which generate the animal heat within normal limits The less important factor is a disturbance of the processes of equalization of the body heat mainly by the action of the skin The importance of exaggeration of heat-producing processes within the body is shown by the excessive consumption of oxygen and the discharge of carbonic acid and urea, a discharge which is compensated for in health by food, which as a certain influence on the quantities of these substances eliminated When, now, we look upon the water formed in the body as an excrementitious product, the formation of which in health is intimately connected with the process of heating, we at once see that the changes seen in most cases of typhoid fever, in regard to the production and discharge of water, become of great importance While in almost all essential fevers there is thirst, the discharge of water by the skin and kidneys is lessened, especially that by the skin The formation of water in health, though with it there is generation of heat, "seems to carry with it the conditions for equalization of the animal temperature by the cutaneous transpiration In simple inanition the tissues are economized by the excessive formation of water and the increased prominence of this process in calorification" With excessive muscular exertion in health there is increased discharge of water But in fever destruction and certain degenerations overtake the fats and solid tissues, and there can be but little doubt that there is diminished formation of water So that, whatever be the essential cause of the fever the matter consumed in the production of the excessive heat is chiefly fat and muscular tissue When in health there is an unusual demand for heat for use in muscular work, there is increased production of both water and carbonic acid, while in fever the increased heat must be supplied by the fatty and solid tissues As these considerations lead to some modifications of accepted views with regard to the theories of fever, and render our ideas more positive and definite than before, Dr Flint expresses these ideas in the form of propositions

1 It is probable that the original cause of most, if not of all the essential fevers is a microorganism, different in character in different forms of fever

2 Defining fever as an abnormal elevation in the general temperature of the body, the pyrexia is due to the following modifications in the normal heat producing processes

A Oxidation of certain constituents of the tissues, probably by reason of the presence of microorganisms in the blood, is exaggerated independently of increased muscular work, and without being compensated by a corresponding increase in the appropriation of nutritive material This increased waste of tissue is represented by the excess of carbonic acid and urea excreted

B The part which the formation of water within the body plays in the production of heat is either suppressed or is greatly diminished in prominence,

together with the equalizing action of cutaneous transpiration

3 Fever produces abnormal consumption of fat, with parenchymatous degenerations, for the following reasons

A The fat is consumed because it feeds the pyrexia more readily than do the other tissues of the body, and its consumption is the most important source of carbonic acid

B Parenchymatous degenerations of muscular tissue and of the solid organs occur, chiefly because the abnormal transformations of these parts, which result in an excess of urea and which probably, also, contribute to the excess of carbonic acid, are not compensated by the appropriation of nutritive matters from the blood

C It is well known that patients with unusual adipose or muscular development are likely to present a more intense pyrexia in fevers than are those whose adipose and muscular development is smaller

Finally *An essential fever is an excessive production of heat in the body, induced by a special morbific agent or agents, and due to excessive oxidation, with destruction of the tissues of the body, and either a suppression or a considerable diminution in the production of water*

Suppression or great diminution of cutaneous transpiration in the essential fevers, while it contributes, in a measure, to the rise in temperature, is not itself a cause of fever

---

Having gone thus far it must be evident that the idea that fever is a conservative process, as some are in the habit of repeating as often as possible, bears the stamp of absurdity upon its face In regard to Dr Flint's discussion of the rational treatment of fever we would advise the reader to again read the "Lecture on the Treatment of Typhoid Fever" by Professor Ziemssen, published in THE JOURNAL of August 27 and Sept 3 In the treatment of fever there are certain indications specially called for by the morbid processes in different systems and organs, all of which have in view, to a greater or less extent, the prevention of injury to the organism by the pyrexia Dr Flint classifies these measures as follows 1 Reduction of the general temperature by the external application of cold 2 Reduction of temperature by the internal administration of antipyretics 3 Promotion of general nutrition by alimentation 4 Measures to supply to the system matters that can be consumed in the excessive production of heat, thereby retarding destruction of tissue In very much the same way, but more briefly, Dr Flint speaks of the use of cold and antipyretics in the treatment of fever "The amelioration of the nervous symptoms and the reduction of the pulse rate, which usually follow reduction of temperature by external refrigeration, are arguments in favor of the view that these symptoms are mainly due to the pyrexia itself, and not to the direct action of the special morbific agent which produces the disease Analogous effects are produced, although in a different way, by internal antipyretic remedies, of which antipyrin and antifebrin are now extensively used in this country in the treatment of fevers

Half a century ago graves were fed by fevers, by the advice of a "shrewd country physician" the process was reversed, and Graves fed fevers We would again refer the reader, in connection with the subject of alimentation in fever, to Professor Ziemssen's lecture It is almost fifty years since Chossat said that inanition is "a cause of death that marches in front and in silence in every disease in which alimentation is not in a normal condition," and in no disease is this more true than in typhoid fever There is an extraordinary physiological demand for heat that must be met by increased alimentation It is by alimentation that we must supply or retard waste of tissue and degenerations when we attain this end we restrain the ravages of fever A less prominent object of feeding is to supply material for consumption, so as to save destructions and degenerations of tissue "The extent to which alimentation, therefore, is to be carried is limited only by the powers of the digestive system" But, unfortunately, we have to contend with degenerations and disturbances of functions of the digestive organs, but there is no doubt that much can be accomplished by the judicious administration of proper foods Far too little attention has been given to those food articles, such as fatty or farinaceous articles, which are of nigh heat value Bearing upon the question of the value of fats in conditions involving excessive production of heat, Dr Flint mentions their value in phthisis "Leaving out of consideration, for the present, the effects of alcohol, there is no measure in the treatment of phthisis of greater recognized therapeutical value than the administration of fats"

That in many cases of disease alcohol has been more abused than used is too well known to admit of discussion, in fact, there are few drugs that have been, and are still, used so indiscriminately and injuriously as alcohol "In no case of disease," says Dr Flint, in speaking of the use of alcohol in fever, "except, perhaps, in certain instances of poisoning by animal venom, should alcohol be administered to a point where the slightest degree of alcoholic intoxication is apparent Alcohol is a potent agent in the treatment of fever, and the clinical guides which should direct its administration are easily recogniza-

ble" In accordance with the views presented by Dr Flint, the excessive production of heat in fever is a fixed condition, continuing for a period which is limited by the duration of the disease The rapid pulse and the nervous phenomena are secondary to the pyrexia, and the parenchymatous degenerations are the more remote changes of tissue which are secondary to and result from transformations involved in the long continued excessive production of heat Therefore, "any readily oxidizable substance artificially introduced will, if it be oxidized, mitigate the secondary effects of the fever upon the pulse and nervous system and retard degeneration, provided always, that it do not increase the intensity of the pyrexia Experience is not wanting to show that these results follow the judicious administration of alcohol in fever" As has already been shown, also, inanition is a constant element in a fever of long duration The disturbance of the heat-producing processes, in which the solid tissues are consumed and the production of water greatly lessened, is one of the most constant and marked conditions of fever In treatment we must endeavor to restore the normal relation between the consumption of the so called solids and the formation of water, as factors in the production of heat The condition of the digestive organs in fever is such that we cannot give fatty and farinaceous foods in sufficient quantity If we could give them in the desired quantity the use of alcohol would be unnecessary But these articles must be prepared by the digestive organs for absorption, while alcohol requires no such preparation, but is promptly taken up by the blood, and is oxidized even more readily in fever than in health Under proper conditions of the digestive organs saccharine and starchy articles of food, as well as the liver-sugar, rapidly disappear, the starch being converted into sugar in digestion It will be remembered that some years ago Dr Wm H Ford showed the presence of alcohol in small quantity in normal blood, and he attributed it to the decomposition of sugar, and he thinks that the destination of this alcohol must be to a hæmal oxidation or combustion, as a main source of animal heat, a combustion that is not only maintained by the glucose derived from the starchy food, but also from the proximate products of change in the nitrogenous tissues

The theory that hydrocarbonaceous substances are converted into alcohol in the body is in accordance with Dr Flint's view that in the generation of animal heat the production of water is an important factor If alcohol be oxidized in the body water must certainly be produced "In the administration of alcohol in fever, we are really using the hydrocarbons in a form in which they may be immediately oxidized and do not require preparation by digestion Thus we easily supply material to meet the excessive waste involved in the pyrexia, in much the same way as we administer peptonized albuminoids to meet the excessive waste of the nitrogenized parts of the tissues when the digestive organs are impaired" Clinical observation has sufficiently shown the tolerance of alcohol by phthisical and fever patients, this tolerance, says Dr Flint, of an article which is probably never useful in perfect health, is strong evidence of a demand on the part of the system for the class of alimentary principles, the hydrocarbons, which alcohol represents, and it affords an absolute guide as regards the quantity that should be employed "With an alarmingly high temperature, a rapid and feeble pulse, and grave ataxic symptoms indicating impending death, alcohol may be given largely, but never to the extent of producing its characteristic toxic effects In fever only such quantity of alcohol as is readily oxidized is useful, and any excess, which will certainly produce some degree of alcoholic intoxication and which must be eliminated as alcohol, will be productive of harm"

According to the author, therefore, the great objects in the treatment of fever itself are to limit and reduce the pyrexia by direct and indirect means, to limit and repair destruction and degeneration of tissues and organs by alimentation, to provide matters for consumption in the abnormal production of heat, and thus to place the system in the most favorable condition for recuperation after the disease shall have run its course

---

The foregoing is simply intended for a fair and concise statement of the views concerning fever presented in Dr Flint's address, which was written in good style and admirably delivered A critical examination, however, will show both his definition and mechanism of fever to be defective, and his theory of the action and value of alcohol and other hydrocarbons in its treatment neither sustained by experiments nor by clinical experience

---

PROCEEDINGS OF THE NINTH INTERNATIONAL MEDICAL CONGRESS —We received early as full an abstract of the proceedings of the Congress as has been furnished to any other medical journal, but so large a part of it consists in simple statements as to who read papers and who took part in the discussions, as is usual in such reports that we do not think it profitable to occupy our columns with it to the exclusion

er delay of important papers previously on hand In leading editorial articles we shall give a fair summary of the general addresses, and under the head of Progress, present some practical items of interest, knowing it to be more just to all parties, that the full Transactions, which will be issued from the press in a few months, should reach our readers with their freshness and interest unimpaired by previous partial or imperfect abstracts

---

DIED, ALONZO CLARK, M D , L L D , at his residence, 23 East Twenty first street, New York, on September 13, 1887, aged 80 years Dr Clark had been for many years Professor of Pathology and Practical Medicine in the College of Physicians and Surgeons, of New York For a brief obituary, see the neurological record on another page

---

RICHARD QUAIN, M D , F R C S , OF LONDON — The secular papers announce the death of this eminent physician and author, at the age of 71 years His name is especially familiar to all students of anatomy

---

SOCIETY PROCEEDINGS

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, April 27, 1887

THE PRESIDENT, JOS TABER JOHNSON, M D , IN THE CHAIR

DR P J MURPHY gave the history and showed the specimen of a case of

MULTILOCULAR CYST OF THE OVARY

Mrs B , æt 33, white, married Admitted to Columbia Hospital for Women, April 11, 1887

History —Has had 3 children—youngest 5 years old, also 1 miscarriage, 1 year ago Menses have been regular from puberty Previous to last spring they lasted 5 to 6 days, since then about 8 days

First noticed a "lump in the side" in June, 1886 It was then near the centre of the abdomen and about the size of her two fists The growth of this lump has been very gradual Has lost flesh since June Appetite capricious Bowels regular Has had no œdema of the lower extremities Menses had not entirely ceased when admitted to Hospital

Examination —A large irregularly-shaped tumor occupies the entire abdominal cavity extending almost to ensiform cartilage By palpation it presents all the characteristics of an ovarian growth or a fibro-cyst of the uterus Per vaginam the uterus is found to be completely retroverted and pushed to the left side The growth is apparently not connected with the uterus proper In the right iliac fossa a round hardened mass is found by bi manual examination which is believed to be a tense minor cyst The diagnosis of a multilocular cyst was made

The usual operation was performed, under ether, April 13 On opening the peritoneum and drawing off the contents of the major cyst, the portion of the growth occupying the right iliac fossa seemed to be attached deeply down to the pelvic viscera The incision was enlarged and some slight adhesions broken down The left Fallopian tube could then be plainly traced into the right iliac fossa It presented the appearance of adherent intestine broadly stretched over the face of the cyst Upon slight traction the semi solid minor cyst was easily extracted As is my custom, a coarse ligature was thrown around the pedicle to secure it and the cyst separated from its attachment The moment the cyst was separated the stump retracted and the ligature slipped off Before the stump could be secured considerable hæmorrhage had taken place into the peritoneal cavity The stump was then transfixed with braided silk ligatures, There was still some oozing from the stump which was controlled by an uninterrupted suture of carbolized catgut The blood that had escaped from the pedicle was then carefully mopped out until the sponges when withdrawn were almost stainless The incision was then closed with 6 deep and 4 superficial sutures and dressed in the usual manner

The weight of the tumor, including its fluid contents, was 15¼ lbs , av , the fluid contents 13¾ lbs av

The patient has made an uninterrupted recovery She required only one administration of morphia to control pain and that on the first day Her temperature went above 101° only twice—once on the 7th and once on the 9th day

DR A F A KING, then read a paper entitled

DYSTOCIA FROM SHORT OR COILED FUNIS

(See p 398)

DR A Y P GARNETT believes that Dr King exaggerates the difficulties produced by a short cord He doubts whether a short or coiled cord can ever be undoubtedly ascribed as a cause of delay, as there are so many other causes of protraction, as, for instance, large head, narrow pelvis or unyielding soft parts, which might have been present in any given case He has never had protracted labor from short or coiled funis It is impossible to accept the statement that the umbilical cord in such cases would alone resist the force usually applied in a forceps delivery, without its being torn from its placental attachment separating the placenta and being itself divided, as we know how easily these accidents may happen by traction on the cord after the birth of the child He had a case with recurring hæmorrhage during the fourth month and finally a miscarriage in the fifth month, when the fetus was expelled in its envelopes He then found that the cord was abnormally attached to to the placenta about 2 inches from the umbilicus He attributes the miscarriage in this case to the growth of the child pulling away the placenta from the uterus at a point opposite the attachment of the cord The condition was a pathological one however (*Am Jour Med Sc* , Jan , 1880) He

could not agree with Dr King that mere gravity, from change of posture, could possibly overcome the dystocia from a short cord

DR H D FRY remarked that Dr King had not given us the very important point of how to make an antepartum diagnosis of coiled or short cord He has enumerated the symptoms given in the books, but as yet no positive symptom has been discovered

DR SCHATZ, of Germany has noticed a change in the rythm of the fetal heart beats in such cases At short intervals he claims that there is a reduction of the heart beats by about one-half The posture recommended by Dr King is, however, of value in obstruction from any cause whether delay is due to perineum or short cord

DR S C BUSEY has never seen an actual short cord, but has so often observed coiling of the cord that he is surprised when he does not find it From theoretical considerations he could believe that a short cord might be a factor in delaying labor but he has not observed such a result If it is such a common cause of dystocia as Dr King asserts, it would be supposed that we would more frequently have premature detachments of the placenta and antepartum hæmorrhage He does not doubt the value of change of posture in some cases of delayed labor, but he did not know that Dr King's explanation of its action is correct, for the same effect might follow a change of posture when the patient was anæsthetized He had seen labor expedited by a change from the dorsal to the left lateral position, and he always preferred the latter position because he believed it promoted the advancement of labor

DR P J MURPHY believes that experience is a better teacher than the platitudes of the books so often quoted In his 15 years of hospital experience he has never seen dystocia from a short cord, and he agrees with the preceding speakers that hæmorrhage would be more common if a short cord were retarding the advance of the child As to the posture for hastening labor in these cases, every old granny has tried that, and he cannot see how it can be of the remotest value, when our whole weight, say 140 pounds, put upon the forceps, has failed to deliver the child For his part he does not pretend to understand the mechanism of labor, nor can anyone else make out the position or feel the fortanelles in a case of protracted labor If men say they can they lie He can tell a head from a tail, but that is all

DR GARNETT inquired of Dr King the *rationale* of the effect of change of posture If, as is claimed, the posture acts through gravity assisted by the abdominal muscles causing the descent of the womb, why does not the whole, full-term gravid uterus engage with the head in this superior strait? This we know does not take place The contractions of the fibres of the uterus are concentric, and are entirely independent of the subsidiary and incidental contractions of the abdominal muscles This is shown when a parturient woman is fully under the effects of ether

DR BUSEY thought that Dr Murphy ought to explain what he meant by his assertion that no man can make out the position of the head in protracted labor Such a statement is altogether too sweeping He is aware that with a large "caput succedaneum" it is often difficult to feel the fontanelles, but even then by proper manipulation it is possible to make out the fetal head position

DR MURPHY modified his statement, saying that when called upon to a case of protracted labor, one does not always have the opportunity of making the required manipulations

DR KING said that he had not brought forward any theories to night, as the gentlemen seemed to think, on the contrary he thought they were theorizing He had stated facts and could show cases to prove his statements He thought that short or coiled cord was a much more frequent cause of dystocia than is usually suspected, but the dystocia is not necessarily dangerous to life—it may only add some hours of suffering Men who did not bear this cause of dystocia in mind would be apt to overlook it after the birth of the child

In reply to Dr Fry he stated that he had given the symptoms of short or coiled cord in a previous paper which he had referred to to-night He expressed his surprise at the force that Dr Murphy advocates using on the forceps He has always maintained that only the strength of the arms should be used in forceps delivery

DR BUSEY asked to be allowed to quote from a previous paper of Dr King's In this he seems to have thought differently about the liability of the cord to rupture or the placenta to be detached "The strongest cord will bear a resistance of 15 pounds before rupture, the average cord 8¼ pounds (Duncan), but instead of our traction force being expended *solely* upon the cord, some of it (we know not how much) is or may be spent in stretching the placenta, or partially separating it from the womb, or in indenting the uterus at the placental site, or in pulling the whole uterus down into the pelvis, or in compressing the soft parts of the fetus round which the cord is coiled"

DR KING said that detachment of the placenta might possibly be prevented in some cases by the placenta being pinched between the uterus wall and the body of the child This had just occurred to him

DR FRY said the uterine wall is sometimes drawn in by traction on the cord—this did not show any such pinching of the placenta

DR GARNETT again said that he would expect rupture of the cord or separation of the placenta, if so much force was required to bring out the head

DR KING said that Dr Garnett's remarks were based on theory while his own were founded on the facts in observed cases He admitted the truth of Dr Fry's statement, but it was one of the possibilities which he had already stated in the paper spoken of before (*Am Jour Obstet*, April, 1881)

ST LOUIS MEDICAL SOCIETY

Stated Meeting, April 9, 1887

THE PRESIDENT, S POLLAK, M D IN THE CHAIR

DR L BREMER read a paper on

MODERN TESTS FOR HYDROCHLORIC ACID — ABSENCE OF HCl IN THE CANCER OF THE STOMACH

The therapy of the stomach and its physiology have made rapid advances of late, but even in modern books, the delicate diagnostic tests of the gastric juice, which have been recently discovered are not mentioned There is no allusion to the methyl violet or co tropeoline tests for hydrochloric acid in the gastric secretion It might be asked Suppose we have a means of detecting cancer of the stomach by a certain means of chemical reaction, what good can it ever do? The answer is In order to know a curable disease, we must know the incurable ones An early differential diagnosis from other more harmless affections of the stomach is of the greatest import If there is, in any given case, an excess of acid production, the supposition is that there is too much lactic acid, and the proper remedy here is carbolic acid to kill the organisms that produce the lactic acid fermentation If, on the other hand, by withdrawing fluid injected into the stomach I should ascertain that there is an exaggerated production of hydrochloric acid, that treatment would amount to nothing, and I would try to lessen the formation of HCl by reducing the patient's allowance of salt

There are two reagents which have superseded the silver nitrate and enable us to detect even minute quantities of HCl in the gastric juice Both are aniline dyes, the one, methyl-violet, a basic, the other tropeoline, an acid aniline color A solution of methyl-violet, (1 grain to 6 ounces of distilled water) being violet in color, turns blue on the addition of very dilute HCl, such as occurs in the stomach, namely 0 03 per cent A tropæoline solution (1 grain to 6 ounces), being of a straw yellow color turns red on the addition of the HCl in the state of dilution as ordinarily met with in the stomach

Not only by distillation, as shown by Claude Bernard many years ago, can HCl be evolved from a mixture of lactic acid and common salt, but even at ordinary temperatures does a decomposition of NaCl take place by the presence of lactic acid Thus an apparently paradoxical chemical process in the stomach can be imitated outside of it, and serves to facilitate the comprehension of the production of free HCl

"If a dilute solution of methyl violet (about 0 03 to 200) be prepared and distributed in three clean test-tubes, and if to one of them dilute lactic acid is added, the color will show a bluer tint than it had before The adding of the acid must be stopped while the color is still distinctly violet To the contents of the second test-tube sodium chloride solution is added, there is no change of color If, now, ½ of the first tube and ½ of the second be poured into a fourth empty test tube, it will be seen that the mixture is distinctly bluer than that which contains the addition of lactic acid It will depend on the degree of concentration of the methyl-violet solution and the lactic acid solution whether the difference is more or less distinct If there were only a simple mixture, the color in the fourth glass would be of medium intensity, the distinctly blue color can be attributed only to HCl being set free"

In order to demonstrate lactic acid in the gastric juice, Uffelmann's test is the most reliable and convenient The lactic acid contained in the secretion is taken up by sulphuric ether, this is evaporated and the residue subjected to the following test

A fresh 4 per cent solution of carbolic acid is prepared "To 10 cc of this solution add 20 cc distilled water and 1 drop of the liquor of the perchloride of iron The amethyst blue color is made yellow by adding ½ to ⅓ of its volume of dilute lactic acid Equally safe is a solution of 1 drop of the liquor of the perchloride of iron in 50 cc of distilled water This, too, is made yellow by lactic acid

This is a very exact test for lactic acid, and it is only the lactic acid that turns the carbolic with the ferric chloride, yellow Neither of the spurious acids in the stomach, butyric or acetic, will make the color turn yellow All of these reactions can be made in an extremely simple manner When I know how the stomach of a patient is, I feel like a man that is not going it blind And there is nothing in the whole realm of therapy which is so satisfactory both to the physician and the patient, and, as a rule, so certain of good results as a rational treatment of digestive disorders and the general disturbances caused by, or associated with dyspepsia, provided, of course, that the patient follows directions and curbs his appetites The American nation is noted for its dyspepsia, and on account of its dyspepsia for its nervousness To get rid of dyspepsia is to mitigate nervousness and the whole of the nervous diseases which are the bane of the present generation

DR ADOLPH GREEN said When Dr Bremer says that if we want to treat nervous diseases, we must treat the stomach, it is true, in a great many cases If you ask another neurologist he will tell you that if you want to cure the stomach, you will have to cure the disease of the nervous system Again a gynecologist will tell you that if you want to attend to digestion you have to first attend to the genital apparatus That is also true in a great many cases, because of the intimate sympathy existing between those organs The judicious physician will, therefore, look over the whole field when he wants to treat the disturbance of any organ, with the exception of those diseases which we know are caused by a certain thing, as infectious and contagious diseases

DR D V DEAN said As regards the absence of hydrochloric acid in the stomach in cases of cancer of that organ as a positive point of diagnosis, I am not entirely assured, though I am not committed against it, nor have I a desire it should not prove a valuable diagnostic point To make it of full value, however, we must know why it is absent There can be no successful contravention of natural laws If reactions in the test-tube in the laboratory differ from reactions in the living stomach, the controlling

circumstances in the latter case are the things for us to search out The point has often been made that if in the test-tube lactic acid be added to a solution of sodium chloride, the stronger acid will not leave the sodium while it will be set free in the stomach during digestion But if another base be present with which the acid may form an insoluble salt, the acid will leave one base for the other in the test tube, or, if an organic matter be present, under certain circumstances the stronger acid will sometimes leave its base Take as example, solution of silver nitrate in contact with organic matter, especially with light or heat, when the metal will be liberated We use tartaric acid in Fehling's solution to enable the alkali to hold the copper-protoxide in solution that another organic substance—sugar—may reduce it to the suboxide So, if we add sodium chloride to 1 solution of albumen and lactic acid to another solution, no precipitate is formed in either But add the 2 resulting solutions together—either in the test-tube or in the stomach, and albumen will be precipitated by the hydrochloric acid liberated from the sodium chloride The lactate of sodium, as Dr Bremer says, is absorbed

Granting that hydrochloric acid is the chief acid in stomach digestion, and that a part at least comes from the peptic cells, if it be true that no hydrochloric acid is found in the stomach in cancer of the stomach, what is the rationale? While it is now admitted that in normal digestion the diastatic action on starch, commenced by ptyaline, is allowed in part at least, to go on in the stomach, and while the fluid fat may, by the muscular action of the stomach, be more or less broken into globules, still the main digestion in and by the stomach is that of albuminoids connecting them to soluble peptones The portion of the stomach furnishing the large part of the digestive fluid and containing the greater part of the peptic glands is the cardiac portion, that portion in which self-digestion goes on most actively after death Cancers of the stomach develop, as shown by Waldeyer, from the epithelium of the long tubular glands of the stomach, and only secondarily penetrate to the submucous and deeper tissues The great majority of cancers of the stomach are at the pyloric end, less at the œsophageal portion They are very rare in that portion, containing the peptic glands and furnishing the peptic secretion It is only intermittently, normally, that this digestive fluid is formed, and that after and during meals or the ingestion of albuminoids They only normally excite this secretion It is not claimed by physiologists that the fluid obtained by irritating the secreting part by a catheter is a perfectly normal gastric juice In cancer of the stomach we largely avoid the albuminoids as food, and give predigested food or such foods as will be digested in the tract beyond the stomach So much gastric juice is not developed, and this may be one reason or the reason that less, if not no hydrochloric acid is found in cases examined In cancer of the stomach pain is more or less constant, and food is refused In ulcer of the stomach pain occurs after taking food to relieve hunger, and the food is thrown off, relieving the pain, but exciting the digestive act Hence, hydrochloric acid may be developed

DR H C DALTON read the history of a case of

MALIGNANT EMPHYSEMA

Before reading the report of this case, I will state that I called at the house of a friend of this patient, from whose house she came to the hospital, and learned from her that the patient came to her house two days before admittance to the hospital, and had informed her that she had a miscarriage about January 15, and that she was also miscarrying at that time The history of the case is as follows

Tillie C, married, entered the hospital March 15 She gave her occupation as seamstress Diagnosis by Dr Bremer after autopsy, *malignant emphysema* She stated that there was no consumption, scrofula, gout dropsy or insanity in her family She had a sister who had fits *Her constitution and general health* had been poor She had pneumonia five years ago, followed by cerebro spinal meningitis, she had ante partum hæmorrhage 4½ years ago She stated that present sickness commenced about a month ago with general muscular lassitude, menstruation came on and lasted one day, this was followed by intense headache, bowels constipated She took laxatives, and bowels have been loose most of the time since

About a week ago she vomited several times, vomited matter was of a greenish color Had not vomited since, until last night She has no appetite, tongue coated, liver slightly enlarged and tender Patient is jaundiced The whole right pectoral region and arm is swollen and crepitates on palpation Patient has considerable pain in right breast and arm, respirations are hurried and deep Passages last night and this morning were loose and tarry Patient is menstruating at present She stated that she had hæmorrhage from lungs several times two or three years ago, had night sweats and cough, lost in weight and had œdema of feet

Many small punctures were made in right breast to allow the escape of the accumulated gas, which had an odor of sulphuretted hydrogen gas, respirations became more rapid and difficult, lips and finger-tips cyanosed, extremities cold, emphysema extended up to the neck and almost over the entire chest She died at 6 15 P M, March 18 The case being of such great interest, I invited Dr Bremer to see the autopsy, which was made 17 hours after death

Autopsy —Body of a well developed woman Chest, right shoulder and neck are puffy and discolored, color ranging from a bluish green to a dark brawny red Rigor mortis present Crepitation of subcutaneous tissues obtainable in throat, thorax, abdomen and upper extremities General, but slight, jaundice Superior longitudinal sinus contained light colored clot Spleen normal in size, intensely congested, no blood flowed from cut surface, tissue soft, friable, crepitated but did not float Kidneys larger than usual, flabby, much congested, capsules stripped off easily, leaving a granular indented appearance of their surfaces Stellæ Ver huynii prominent Both kidneys crepitated on pressure and floated in water Liver of normal size, crepitated, but did not float in

water Crepitation noticed in walls of stomach, which was congested at its cardiac end, externally and internally, contained a considerable quantity of greenish fluid Uterus 10 cent (4 in) in length, contained dark-colored material of the consistence of jelly The organ emitted a fetid odor, its tissue was firm, but crepitated and floated in water Heart tissue was soft and friable, crepitated and floated Serous linings of aorta showed evidence of recent inflammation Heart cavities contained clots of red dish brown color, which crepitated and floated in water

Before the thoracic cavity was opened, air was forced into the nose, the mouth being closed, it went directly to the stomach The anterior wall of the trachea was then perforated, and through this the lungs were inflated fully, but no air escaped from thoracic walls This was done to determine whether or not the emphysematous condition proceeded from the lungs The right pleura was also inflated by a hole through its external wall and was found to be intact The cellular tissues beneath the integument of both arms, right forearm, throat and abdomen were infiltrated, the air having the odor of sulphuretted hydrogen Its color here was dark with a red dish tinge, seeming to be in an early stage of gangrene No point of origin for the emphysematous condition could be discovered

The internal mammary, subclavian and its branches, axillary and brachial arteries were found to be clear, likewise the accompanying veins, with the exception of the venæ comites brachialis, which contained a soft, dark colored clot, beginning at a point 13 cent (5 in) above the elbow joint, and extending to the shoulder joint, having a length of 10 cent (4 in) The vessels of the left upper extremities were empty

It will be noticed that there was an emphysematous condition of many of the external organs The case is very unique and an extremely rare one I think the whole trouble due to the miscarriages

Dr Bremer The essential point in the case was the extensive emphysema of the integument, which, when punctured, emitted a fetid gas The gentlemen who made those punctures state that it was sulphuretted hydrogen gas Of course the subcutaneous emphysema suggested the lung as its origin There might have been a fracture of a rib, agglutination between the pleural layers and a communication established between the lung and the subcutaneous tissues Such a supposition was excluded by the fact that there was a terrible odor to the gases which escaped on puncture That suggested at once the idea that we had to deal with a malignant process, and in the absence of any better name I suggested the term "malignant emphysema " There is a disease of cattle, met with in Germany and France, and which also sometimes decimates the horses of those countries It is called "Rauschbrand" or gaseous gangrene Koch, years ago, established the very important fact that when ordinary earth, or dust, or the blood from decomposing animals, especially as phyniated animals, is introduced into the blood of a guinea pig or rabbit, there is set up a peculiar disease which runs a rapid course, with high fever, which is characterized pathologically by the existence of œdema, and at times by emphysema of the skin This disease was termed by Koch "malignant œdema" The older members of the profession will certainly remember that horrible complication of gangrene with emphysema occurring sometimes in complicated fractures and deep lacerated wounds in the pre antiseptic days In our days it is of rare occurrence

A French author, Tuffaud, about two years ago published a paper on what he calls *gangrène gazuse foudroyante*, as occurring after amputation There have been published in all about 123 cases of traumatic gaseous gangrene, in which the injuries were trifling compared with the fatal affection that ensued

Brieger and Ehrlich injected tincture of musk into the thighs of a number of typhoid fever patients at the Charité in Berlin, all of them got well, with the exception of two, in which malignant œdema and emphysema started from the point of injection, travelled upwards, and the two died within three days The same pathological lesions were found in these cases as in the case detailed by Dr Dalton These two observers came to the conclusion that in all probability the virus that gives rise to the malignant œdema was contained in the tincture bottle, and that it was injected and set up the disease Unfortunately, the bottle had been lost and the theory could not be verified by actual experiment At all events it seems clear that whenever a patient is suffering from infectious disease, the accidental introduction of certain germs may set up the complication of malignant œdema As a rule, man is not very susceptible to the poison, it seems that he must be debilitated by another infectious disease in order that the germ of malignant œdema may multiply in the system Brieger and Ehrlich remembered that they had seen a case of diphtheria in which emphysema had taken place They had simply noted it as a very peculiar phenomenon afterwards, in the light of later knowledge acquired, they set it down as a case of malignant œdema

The micro organism of malignant œdema is a bacillus of various sizes It seems that there is not one organism, but a number of them, in the case of experimental œdema If some earth, especially such as contains manure, is introduced into the skin of an animal (mouse, rabbit, guinea pig), there will be a general infection, the animal dies within two or three days If now one drop of blood from this animal be inoculated into another, the same disease will be produced There is a limit to this, however With the third animal the virulence comes to an end, it does not take on the fourth subject Koch separated the bacillus which in the pure state would produce the diseased condition, minus, however, the emphysema, there was only œdema He concluded then that there is another parasite which produces the gases We know that, in the common process of putrefaction, gases are produced in the body This is the work of the micro organism of putrefaction The terms bacterium termo and b lineola, to which the putrefactive process is generally attributed, comprise a great many organisms, and are not distinct

species As regards our case, I obtained and examined pieces from almost all the organs of the body, with the exception, I am sorry to say, of the brain And I found that the whole organism was fairly swarming with bacteria It must, however, be taken into consideration that the post mortem took place 17 hours after death It has been demonstrated that the bacillus of malignant emphysema will multiply after death, this is not the case with other bacterial diseases So a great many of the micro organisms seen in this case are of post mortem growth However, it was demonstrated that this material was extremely malignant, two mice and one rabbit inoculated with it died in 18 hours, and their bodies were found to be swarming with these identical organisms

I examined the spleen which looked perforated and worm eaten, and in the spaces that are even seen microscopically, there are numberless organisms demonstrable The holes are due to the expansion of the gas elaborated by bacteria This is characteristic of malignant emphysema The same was to be observed in the liver, uterus and ovary, and in the right pectoralis major muscle, which was chiefly involved The latter was a brittle mass, and the muscular tissue was broken down In certain places there was fatty degeneration of the muscle fibers, small and large fat globules were contained in the sarcolemma The subject being a female, there was a great deal of adipose tissue, and also intra muscular fat which was partly in a free state—the connective tissue capsules surrounding every fat globule having disappeared

The liberation of fat globules is the work of the microorganisms which destroy the connective tissue capsules The fat, then, met with in the broken-down muscular tissue, has two sources, one in the fatty degeneration of the muscle fibers, the other in the liberation from its connective tissue capsules of the adipose tissue

In the liver there was an immense number of bacilli The spleen, kidneys, ovaries and uterus all looked worm eaten, the holes being in places, filled by bacilli When I saw this case first and observed the pathological changes, I requested Dr Dalton to inquire into the history of the patient and see if she had not had an abortion, because there must have been some entrance for the germs It was quite improbable that the bacteria should have entered by the intestinal tract The doctor found that she had produced an abortion on herself once 3 months ago, and again recently The cavity of the uterus was coated with a black mass, and testified to recent hæmorrhage The whole uterus was perforated by the organisms, large spaces which were made by them had been distended by gases during life It is probable that the abortion had been produced with an unclean instrument The patient had been sick before, else infection would not have occurred, because it has been demonstrated (Brieger and Ehrlich) that malignant œdema in man does not occur except in conjunction with some other disease

As to the lungs, there was a very peculiar state, and one which is not very frequently seen You will remember that persons having sustained complicated fractures sometimes die very suddenly, with symptoms of asphyxia The death was due to fat embolism of the lung The fat from the yellow marrow is absorbed by the broken veins, carried to the right heart, thence to the lungs, and the smaller pulmonary vessels are stopped up by the fat giving rise to dyspnœa and eventually to asphyxia

In addition to the microorganisms which were found everywhere in the lungs in great numbers, I found many capillaries clogged by fat Where did the fat come from? You will remember what I demonstrated here in these muscles, in the first place the muscular tissue becoming degenerated, and in the second place the fat being set free The fat was absorbed by the broken veins, or may be, by lymphatics, and in the same way, as in fractures, went to the right heart and thence to the lungs So this woman died from the infection and also from fatty embolism of the lung I don't believe that there is, at present, a case on record in which this combination has been observed I don't doubt that it occurs not unfrequently Fat was also observed in the capillaries of the kidneys Fat embolism is frequently the cause of death in diabetic coma The manner of its production is not understood

In conclusion, I will say that all the organs of the body were brittle, I tried to make microscopical sections of the heart, but could not do it because the whole substance crumbled down Extreme brittleness and friability must have been the result of the noxious substances secreted by the bacteria

These observations warrant the following conclusions

Abortion when produced with unclean instruments on a person debilitated by previous disease, may give rise to malignant œdema and emphysema (general gaseous gangrene) As a complication fat embolism of the lungs and kidneys may arise

DR ADOLPH GREEN said This expression of "malignant emphysema" is a very good one But as to fat embolism of the lungs, as much as I know, it takes place usually by osteo-myelitis, spontaneously in contra-distinction to that of traumatism The majority of cases of fat embolism are from contagious diseases, consequently, that specific organism that causes osteo-myelitis is self circulating in the blood It attacks the bone and liquefies it, and as there are veins ruptured, fat is taken to the lungs in the form of embolism

DR D V DEAN said As regards the case reported by Drs Dalton and Bremer, it is not new to me, and I think most of us here have seen such cases, but have passed them under the name of septicæmia All the changes mentioned as occurring in the tissues in this case, including the liquefaction and flowing together of the fat, are common, according to the degree in all local or general gangrenous emphysema or, as it is sometimes called, fulminating or gaseous gangrene I have recognized cases of septicæmia or putrid infection as due to malignant bacteria, but not with such microscopical analysis or refinement of diagnosis as to designate the case one of malignant œdema, or malignant em

physema Davaine's septicæmia, made known in 1872, produced by injecting putrid beef-blood into the subcutaneous tissues of the rabbit, similar to Koch and Gaffky's septicæmia produced by injecting water from a foul rivulet, putrid matter, etc , is inoculable from animal or animals, and attributed to a bacterium It would be well, I think, if we were to drop the term bacterium except for the groups, as is suggested by DeBary, Ranvier and Babes, and others, to avoid confusion Malignant œdema of Koch and Gaffky is the same affection called Pasteur's septicæmia, and the bacillus of œdema appears to be identical with Pasteur's vibsion septique or vibrio septicus It produces emphysema as well as œdema. Pasteur complained that it was often confounded with bacillus anthracis by those who attempted to imitiate his inoculations for immunity from anthrax The vibrio is anærobic and will thrive in a vacuum and in carbonic acid, while the anthrax bacillus is ærobic As soon as the patient dies of charbon the bacillus anthracis begins to be replaced by the septic vibrio or malignant bacillus, so that in 24 hours the bacilli are all of the malignant kind, and those who procure blood for culture at that time use material just as fatal as that from anthrax, but very different in kind and in effect

Rauschbrand in its grosser aspects, I have been familiar with since my early boyhood, under the name of symptomatic anthrax, black leg, quarter evil or quarter-ill, so called because of its visible manifestation (emphysema and hæmorrhagic effusions occur in one or more quarters of this animal) Using the terms malignant emphysema, gaseous gangrene, fulminating gangrene, etc , for the affection proven to be due to specific malignant bacilli, the so called bacilli of malignant emphysema, we have to engraft a finer pathological knowledge upon our previous coarser knowledge of symptoms This disease is quickly fatal and communicable to man, while malignant œdema became known to us as an experimental or experimentally-produced disease But there is no reason why either affection may not come to man by accident The patient told conflicting stories To the doctor she said she was menstruating, while a day or so before she told the woman friend she (patient) was having a miscarriage The latter account would furnish the best probability that the septic organisms entered by way of the uterus Impure or earthy water may have been used also in injections, though the publication of Davaine's studies of charbon, in 1862–3, went far toward proving the etiology of the disease Koch's "Etiology of Anthrax," based on the history of development of bacillus anthracis, published in Cahn's *Beiträge, 1876*, the year I took charge of our City Hospital, gave a new impetus to my mycological studies, especially as they related to infectious diseases But in 1878 came Koch's "Investigations of the Etiology of Wound infectious Diseases" The study of this work and of what grew from it had great influence on my future course, and with the latter experiments of Koch and Gaffky and others with garden-earth injections subcutaneously in the production of malignant œdema or Pasteur's septicæmia, caused me to resolve to permit no dressing of wound with materialized earth, during my administration of the hospital, though earth dressings were quite fashionable with some of our advisers

Pasteur thought the vibrio septicus to be the cause of commencing cadaveric putrefaction Dr Bremer alluded to the part played by bacteria in stomach digestion and spoke of putrefaction of the body as a kind of bacterial digestion He also spoke of the cases of typhus in which Brieger and Ehrlich produced extensive œdema and emphysema by injection of tincture of musk, and in which they found, after death, the bacilli of malignant œdema that had probably come from the tincture baths and multiplied, producing the complication in the already diseased bodies He also alluded to the case of diphtheria in which malignant emphysema occurred It appears that when the body is affected by ever dangerous bacterial disease, if these malignant bacilli gain a footing they rapidly pass through the body and cause death But great as is our danger from pathogenic or malignant bacilli, we are as much dependent upon benignant bacteria for our maintenance It is somewhat the fashion now to use digestants as a local application in diphtheria Recently papayotin has been lauded as a local application in diphtheria

The unfortunate feature in the case before us is that its character was not recognized before death, and the autopsy was not held until 17 hours after death, when the bacilli that cannot be distinguished from ordinary putrefactive bacilli had taken complete charge of the body, and it was too late to attempt pure cultures or the experiment of inoculation upon animals, with any but mixed results Under the most favorable circumstances it would require most skilful work to differentiate and single out the specific malignant bacilli, respectively of malignant œdema and of malignant emphysema In view of the clinical history I think the diagnosis malignant œdema would practically cover the ground as far as there is actual proof Accompanying œdema in most of these malignant cases there is emphysema also As the bacillus œdematis may live in carbonic acid, so the gas may as well have been carburetted as sulphuretted hydrogen, as is in part the case in intestinal gas I am not aware of the publication of a case in this country with such analysis and diagnosis as in this one, and the merit lies in the after-death recognition of the elements for diagnosis

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

American Association for the Advancement of Science—Water Purification—Summer Corps of Physicians of the Board of Health—Sickness on Ship board from bad Water—Provision for the Insane

The annual meeting of the American Association for the Advancement of Science, which met here

during the second and third weeks of August, attracted much less attention than it would have done had the meeting occurred at any other season than that at which New York is most completely emptied of those who would naturally take the most interest in a gathering of this kind Still, the attendance has been large, amounting to 728, and the members have shown their interest by contributing some 250 papers to the various Sections of the Association Among them have been quite a number of special interest to medical men, such as those by Professor Alfred R Leeds, of the Stevens Institute, Hoboken, on "The Scientific Basis of the Feeding of Infants," "The Causes, Progress and Cure of the recent great Outburst of Typhoid Fever at Mount Holly, New Jersey," and "The American System of Water Purification" The essential features of this system are the following 1, artificial aeration under pressure, 2, precipitation of dirt, sewage, hardening constituents, and coloring matter by harmless precipitants, 3, mechanical filtration through filters capable of rapid reversal of current, and cleansing by mechanical means

Other papers worthy of special mention were "The Physiological and Pecuniary Economy of Food," and "The Food of Workingmen, and its Relation to Work Done," by Prof W O Atwater, "Color-Blindness among Railroad Employés," by Dr William Thompson, Professor of Ophthalmology in Jefferson Medical College, Philadelphia, and "A Review of the Data for the Study of the Prehistoric Chronology of America," by Dr Daniel G Brinton, of Philadelphia The sessions were held in the attractive new buildings of Columbia College, and were opened by a cordial address of welcome from the Rev Dr F A P Barnard, President of the College The entertainments offered the visiting members and their families included a handsome reception and promenade concert in the Metropolitan Opera House, and a number of pleasant excursions to points of interest in the vicinity of the city The main purpose of the Association, which is to encourage social intercourse among men of science, was kept in mind during the meeting, and a good deal was, no doubt, accomplished in that direction This view of the office of these meetings was well expressed by Professor Langley, the distinguished astronomer, in replying to President Barnard's address of welcome "Wherever two or three among us are gathered together," he said, "it is a happy thing that we cannot remain strangers, for doubtless of the many here who have continually breathed 'the calm and still air of delightful studies,' there are few but know by experience how hard it is for one coal to keep alight alone, and how especially good it is for the solitary thinker to be brought at times into the warmth of companionship"

The address of the retiring President, Professor Morse, of the Essex Institute, Salem, Mass, was a review of what has been done of late years toward a demonstration of the truth of the theory of evolution, of which he is an enthusiastic advocate Prof J W Powell of Washington, Director of the United States Geological Survey, was elected President for the ensuing year, and Cleveland was selected as the place for the next meeting, which begins on the fourth Wednesday in August, 1888

During the past two months much good work has been accomplished by the summer corps of physicians of the Board of Health, a service which had to be abandoned last season, on account of there having been no appropriation made for its maintenance Unusual care was taken in the selection of the fifty physicians of the corps this year, each applicant being required to pass a Civil Service examination, and special pains have been taken to secure a thorough performance by them of all the duties required of them Some idea of the work done by the corps may be obtained from the following statistics of a single week, as reported to the Board of Health by Dr Moreau Morris, Chief Inspector of the Summer Corps 4,561 tenement houses, containing 30,704 families, were visited, 1,089 cases of illness prescribed for, 153 complaints of the unsanitary condition of premises made, and 3,164 sanitary circulars and 1,512 tickets for the free excursions of the St John's Guild Floating Hospital distributed The diseases met with are classified as follows 496 diarrhœal, 23 dysenteric, 130 respiratory, 38 contagious, and 398 miscellaneous In the course of some remarks to the members of the corps at the commencement of the service, Health Commissioner Bryant gave the following excellent advice "Teach the poor people that you are their friends, and you will inspire them with confidence Do unto them what you would expect to have done unto you under similar circumstances Do not be carried away with the idea that you are a Board of Health representative and have great authority, but be gentlemen If you find that some families, where a contagious disease exists, have employed a family physician, avoid making a diagnosis merely to confirm that doctor's views Such a course is unprofessional and unmanly Learn the origin of the disease, and advise with the regular medical attendant as to the best methods to be devised to check a spread of the disease among the families in the same house or neighborhood"

A case very similar to that recently reported in THE JOURNAL, in which impure water was the cause of a serious outbreak of typhoid fever on board the Allan Line steamship "Prussia," has come to light here The vessel in question is the British steamer "G W Jones," which lately came from Guantanamo to this port On her arrival at quarantine it was found that a large number of the crew were suffering from dysentery and malarial fever, and it was ascertained that the sickness was due to the foul character of the water taken on board before the vessel left Aspinwall for Guantanamo At the latter port several men had to be transferred to the hospital

The Committee on the Insane of the State Board of Charities, in the early part of July, made a thorough investigation of the City Insane Asylum, and the report of this investigation, founded upon an immense mass of testimony, which has now been made public, reveals the existence of many abuses in the institution, among the chief of which are the overcrowding and improper feeding of the inmates and the insufficient number and unworthy character of

the attendants Among the immediate measures recommended by the committee for provisional relief are the following

1 The erection and fitting up of suitable buildings on the farm belonging to the city at Central Islip, Long Island, these buildings to be on the cottage plan, none to exceed two stories in height, and all to be inexpensive and in accordance with principles illustrated by the Alt Sherbitz Asylum in Saxony

2 The Board of Charities and Corrections, as soon as practicable, to provide adequate, healthy, and cheerful rooms for all the patients and attendants in the Ward's Island Asylum, to provide food of greater variety and nutritious qualities, to institute schools for the patients and training schools for the attendants, to give increased facilities for healthful and productive labor of the patients on the farm and otherwise, to secure a better classification of patients in the wards, to do all in their power to elevate the office, character and service of the attendants, by reducing their hours of duty, by increasing their means of rest and proper recreation, and so soon as improved accommodations and conditions will create the supply, to increase the number of attendants on acute, violent and filthy wards, and to substitute worthy and competent men in the places of the present large numbers of degraded and demoralized incumbents

3 As soon as the new conditions and environments hoped for make it possible, a provision for the treatment of the acute insane, separate from the care of the chronic insane, under the advice of the General Superintendent of both city asylums, and of the State Commissioners in Lunacy

In order to make the reforms permanent the committee recommends that either the management of the insane should be given to a Board of Trustees appointed by the Mayor, or preferably to that of a single Commissioner, in which case four single handed departments would be constituted to have charge respectively of, 1, the insane asylums, 2, the institutions for children, 3, the hospitals and the almshouse, and 4, the workhouse, city prisons and penitentiary On the omission of the city and county to provide such permanent as well as provisional relief, the committee recommend, finally, that the State shall intervene and assume the care of the city insane

PECULIAR TOXIC OR INTOXICATING EFFECT OF TOBACCO SMOKE

Dear Sir —A gentleman 39 years old, weight 170 lbs, occupation a guide roller, came into my office this evening for examination for life insurance I was smoking a cigar He politely asked me to desist from smoking whilst he was in the office, as he would not hold himself responsible for what might occur I quit smoking and raised the windows to let the offensive smoke pass out He stated that the smoke first caused an intense pain over both eyes, causing him to knit his brows, then he became, as he termed it, cranky, and would fight with his best friend After this cranky condition lasted for a time he became sick at the stomach, and would throw up the contents of his stomach, after which he would have to lie down He further stated that his mother had the same idiosyncrasy with regard to tobacco smoke, and he believed he inherited it from her, his father was a smoker He tells the story of being on a jury once and the jury had retired into a private room for deliberation Some of them began smoking He politely asked them to desist, and all but one did so It was not long till the smoker and he got to words and would have got to blows, but fortunately the tipstave called them to the jury-box, thus preventing the blows He afterwards, when the crankiness had passed off, apologized to the smoker I report this as an exceptional effect of tobacco smoke on an individual JOHN M BATTEN

Pittsburgh, Sept 13, 1887

NECROLOGY

DR ALONZO CLARK

Alonzo Clark, M D , L L D , for many years Professor of Pathology and Practical Medicine in the College of Physicians and Surgeons and President of the Faculty, died at his home, No 23 East Twenty-first street, New York, Sept 13, 1887

Dr Clark was born in Chester, Hampshire county, Mass Singularly, he never knew the exact date of his birth He believed it to be 1807, but others had told him that it was 1808 His father, Spencer Clark, was a large tanner, and in company with Colonel Edwards, controlled the New York market During his earlier years Dr Clark attended the public schools of his native town In 1824 he entered Williams College, being graduated in 1828 He at once began his medical studies and in 1835 was graduated from the College of Physicians and Surgeons, of New York Soon after graduation he was appointed Professor of Pathology and Materia Medica in the Vermont Medical College, at Burlington After a few years spent in lecturing there and attending to his increasing practice, he removed to New York and entered upon active professional duties His success as an instructor had become so marked that he was soon made Professor of Physiology and Pathology in the College of Physicians and Surgeons This position he held from 1848 until 1855 Meanwhile he was gaining a high position as a practitioner of special ability in the diagnosis and treatment of disease

In 1855 Dr Clark was appointed Professor of Pathology and Practical Medicine in the College of Physicians and Surgeons, and in the same year he became visiting physician to Bellevue Hospital In 1853 he was elected President of the New York State Medical Society In 1861 he was made President of the Medical Board and consulting physician to St Luke's Hospital He was consulting physician to the Northeast and also to the Northern Dispensary In addition to the State Medical Society he was a member of the American Medical Association, of the New York Medical and Surgical Society, of

the New York Society for the Relief of the Widows and Orphans of Medical Men, of the New York Pathological Society and of the New York Academy of Medicine

Dr Clark was a general practitioner rather than a specialist, although he paid little attention to surgery and devoted himself almost entirely to the treatment of disease Few physicians were more frequently called in consultation As an investigator he made important discoveries in medical science, some of which have become embodied in medical literature In March, 1866, there was published in the *Medical Record* one of the most pithy and admirable lectures on Asiatic cholera known in medical literature At a meeting of the New York Academy of Medicine, May 9, 1866, Dr Clark discussed the use of morphia hypodermically injected to prevent death from overdoses of aconite, and gave histories of two cases where he had by this means saved life On February 7, 1870, he delivered a lecture at the College of Physicians and Surgeons on "Relapsing Fever," which had then appeared in New York for the first time Among the important papers contributed to medical literature by Dr Clark are "Destruction of One Lung by Inflammatory Phthisis," published in *The Medical Record* January 2, 1875, "Salicylate of Soda in Rheumatism," which appeared in *The Record* October 7, 1876, and "Localized Peritonitis—Prolonged Jaundice—Renal and Cardiac Disease," published July 20 1878

Dr Clark's abilities as a lecturer as well as his high rank in his profession were recognized by his election to the presidency of the faculty of the College of Physicians and Surgeons He was also the personal instructor of many physicians of note who studied medicine in his office Personally Dr Clark was tall and dignified with head usually slightly bowed as if with thought, and with his manner tinctured with a gravity the natural result of the constant cares and heavy responsibilities he had borne through life in his work as a trusted medical adviser But with this dignity was joined an old-school courtesy and a fund of dry wit which was never diminished by the harassing anxieties of a physician's life

A few years ago Dr Clark was succeeded in the presidency of the College of Physicians and Surgeons by Dr John C Dalton

MISCELLANEOUS.

INTERNATIONAL MEDICAL CONGRESS —A special dispatch from Niagara says "The foreign delegates of the International Medical Congress passed the day sight seeing They held an impromptu meeting this evening in the parlors of the International Hotel, over which Dr Pavy, F R S , of London, presided Brief speeches were made expressing a hearty feeling of appreciation of the attentions showered upon them by Americans, and a resolution of thanks, prepared by Mr Lennox Browne, of London, and seconded by Dr Charles Reyher, imperial delegate from St Petersburg, was unanimously adopted" —*Medical Register*, Sept 17, 1887

TRANSACTIONS OF THE CONGRESS —The Secretary General has sent all the manuscript of the General Sessions to the printer, and if there is delay in the publication of the Transactions it will not be his fault Officers of Sections should prevent delay by sending in the minutes and manuscripts of their Sections at once Up to September 20, the Secretary General had received the complete proceedings of two Sections only, viz the Section on Physiology (Dr Callender), and the Section on Public and International Hygiene (Dr Joseph Jones.)

ADVICE TO MEDICAL STUDENTS —The London *Lancet* says We advise students, for their own sake, to cultivate the practical element in their own education, to learn for themselves early the interest of common cases, common remedies, and common causes of disease, to aim at readiness in detecting what is wrong, and in seeing the nature of the correctives that can be applied Our recommendation is not in favor of dogmatism and quackery and a specific for every symptom, but in favor of the cultivation of a medical aptitude for detecting and removing the run of diseases for which people consult medical practitioners No worthy student should wait for the action of medical authorities in demanding proof that he knows the profession on which his living and the life of his patients are to depend

THE SUBSCRIPTIONS TO THE COMMEMORATIVE MEDAL of the Ninth International Medical Congress have proved nearly sufficient to cover the necessary expenses of engraving the die, striking the medal, furnishing a proper case, and mailing the completed medal to the subscribers That all members of the Congress, however, may have an opportunity of possessing this memento, those who have not subscribed can yet do so any time within this month by forwarding the cost, $5 00, to Dr J M Toner, 615 Louisiana Ave , Washington, D C

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM SEPTEMBER 10, 1887, TO SEPTEMBER 16, 1887

Capt H O Perley, Asst Surgeon, ordered to accompany battalion of the Twenty Third Infantry from Ft Wayne, Mich., to Chicago, to participate in the International Military Encampment to be held in that city in October next Par 1, S O 191, Hdqrs. Div of the Atlantic, September 8, 1887

First Lieut Wm N Suter, Asst Surgeon, ordered to accompany battery "E," Third Artillery, from Washington Bks D C , to Philadelphia on the 14th inst , to participate in the military parade, during the celebration of the Centennial of the Adoption of the Constitution, September 15, 16 and 17, 1887 Par 3, S O 191, Hdqrs Div of the Atlantic, September 8, 1887

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY, DURING THE WEEK ENDING SEPTEMBER 17 1887

P A Surgeon Richard Ashbridge, detached from "Constellation" and to the Naval Academy, Annapolis, Md

Surgeon Joseph G Ayers, detached from Torpedo Station and wait orders

Surgeon John C Wise, ordered to relieve Surgeon Ayers at Torpedo Station

Medical Director Samuel T Cones, detached from Hospital, Chelsea, Mass , and placed on retired list September 17

Surgeon George P Brady, leave of absence extended six months, with permission to remain abroad

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE WEEK ENDING SEPTEMBER 17, 1887

Surgeon W H H Hutton, granted leave of absence for thirty days September 15, 1887

Surgeon George Purviance, granted leave of absence for thirty days September 13, 1887

P A Surgeon S T Armstrong, granted leave of absence for thirty days September 13, 1887

P A Surgeon A H Glennan, to proceed to Charleston, S C , for temporary duty September 15, 1887

Asst Surgeon J H White, granted leave of absence for twenty seven days September 13, 1887

Asst Surgeon Seaton Norman, granted leave of absence for twenty days September 16, 1887

Asst Surgeon F C Heath, to proceed to Mobile, Ala , for temporary duty September 15, 1887

SYNOPSIS OF THE SECOND HUNDRED CASES OF STRICTURE OF THE URETHRA TREATED BY ELECTROLYSIS WITH CASES

Read in the Section on Surgery, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY ROBERT NEWMAN, M D,

OF NEW YORK.

(*Concluded from page 393*)

The previous statistics, showing certain points, do not give the history, details and progress of the treatment, which are necessary for a thorough understanding To supply this want I will conclude with a record of cases, partly condensed and partly *in extenso* While space does not permit details of all the 100 cases, typical cases will be given to represent groups

Group I —Strictures complicated with urethral granulations or ulcers, use of the endoscope No 104 E S, Newark, N J, æt 25 years Stricture of urethra, granular urethritis June 26, 1882 Has had gonorrhœa once, 3 years ago Was cured of it in 2 months Noticed a stricture 8 months ago A gleety discharge commenced a few months before the stricture was noticed At present the stream is small, corkscrewed and of less power than formerly Examination with *bougie à boule* finds the walls of the urethra thickened by hypertrophy, there is no increased sensitiveness There are two strictures, respectively 3½ and 7 inches from the meatus The size of the strictures was No 20

June 30 Endoscope shows a large granulation at 6¼ inches from the meatus, which spot was touched with a solution of nitrate of silver A few spots in front are of little importance

July 8 Endoscope A weaker solution of nitrate of silver was applied to different places, where granulations and indurations were seen The parts are improved

July 14 Iodoform was applied through the endoscope

July 17 Electrolysis Electrode No 34 French, bulb egg-shaped Current of 5 milliampères was used for 5 minutes The electrode passed the strictures easily

July 27 Endoscope used, and affected parts painted with a brush with a weak solution of nitrate of silver

July 31 Endoscope Mucous lining red and congested At 6¼ in a few spots covered with pus are touched with the solution

August 7 Endoscope shows improvement, mucous lining has a more natural color, is not congested, and granulations have disappeared

August 31, Oct 10, and Nov 14 Electrolysis was used so that a No 27 French passed very easily Has been under observation 3 years, and was reexamined August 25, 1885

No 129 —Stricture, Granular Urethritis, Endoscope —H A R, æt 52, N Y, widower When 20 years old had a urethritis, which was not thoroughly cured 14 years ago stricture was noticed and treated by gradual dilation At present complains of gleety discharges, soreness in the urethra and a diminished stream on micturition Sometimes has spermatorrhœa with stools Bowels are regular and general condition is good

Sept 19, 1883 Examination with the *bougie à boule* revealed three strictures at 1, 3 and 5 inches from meatus, which a No 14 French would pass The walls of the urethra are thickened and sore on touch The urethra is very sensitive, and bleeds at a touch The electrolytic treatment was preceded by mild injections and the use of Mitchell's gelatine urethral bougies, to mitigate the sensitiveness

Oct 4 Electrolysis with a No 17 French, egg-shaped bulb Negative pole to stricture, which passed all strictures in 6 minutes, 4 milliampères were used, 11 gelatine bougies have been used, and urethra is no longer sensitive

Oct 10 Electrolysis No 20 French passed easily through all the strictures, there is still some soreness

Oct 20 Electrolysis, No 21 passed easily

Oct 29 Endoscope showed an engorged state of the mucous lining throughout the urethra, and granulations Mitchell's urethral bougies continued

Nov 5 Endoscope, large tube (easy), showed improvement, granulations treated locally through the endoscope

Nov 12 Electrolysis with No 23 French, 11 minutes, 3½ milliampères

Dec 3 Electrolysis, No 22 French, easy, 8 minutes, 3 milliampères

Jan 5, 1884 Endoscope Granulations at 5½ in from the meatus were touched with the solution

Jan 10 Endoscopic applications were repeated

Jan 18 A No 26 French steel sound passed easily by its own weight, while a current of 2½ milliampères was used, and did not cause the slightest

irritation Two years afterwards reexamined, found healthy and without any relapse

No 180—W A A, æt 26, New London Had gonorrhœa 3 years ago, was treated by too strong injections Subsequently a stricture was observed and treated by gradual dilation, then by electrolysis Next went to Dr Nelson, of New London, who kindly referred the patient to me

Feb 24, 1886 Examination Active inflammation has continued with constant discharge, and profuse bleeding on the slightest touch Painful erections during the night At 1½ in was a slight stricture, at 4½ in a denuded surface, bleeding on touch, and at 5 in was another stricture which a No 20 French will not pass Weak injections are recommended, and later Mitchell's urethral bougies

During the month of April electrolysis was used, and gradually the calibre of the urethra was enlarged from No 18 to No 28 in 4 seances

May 14 Electrolysis with a No 28, which was almost too large to enter the normal meatus

May 30 Endoscope showed a denuded surface of the mucous lining at 4½ in, where it was treated by local applications

June Well One year's observation, when his family physician reported him well

Group II—Complications with retention, spasm of the bladder, prostatic residue, and over-distension of bladder No 167 Dr G S M, æt 49, widower, Conn For a number of years has suffered from gleet, chronic prostatitis and cystitis, has had constant irritation and frequent micturition There is a discharge from the urethra, and for the last 8 years has suffered from a stricture

Sept 17, 1885 The stricture is at 2½ in from the meatus, the walls of the urethra are indurated, giving a paper like touch in transmitting the instrument There are spasms of the bladder and sensitiveness, particularly in the prostatic region The stricture scarcely admits a No 20 bougie Electrolysis with a No 23 French, acorn bulb, straight electrode, 3 milliamperes, 7 minutes, passed the stricture easily

Sept 27 Electrolysis, No 25 French, acorn bulb, straight This No 25 is as large as the meatus will admit The prostate is improved, there is still a little discharge, but the stricture appears to be cured

Oct 11 and 25 Two more séances of electrolysis with Nos 25 and 26 respectively The meatus was rather contracted, and had to be stretched to admit the instrument, but it was done with patience, time, and without porotomy The urethra was capacious and the electrode passed easily

Jan, 1886 Patient was married last December, and writes that he is perfectly well, prostate is not sensitive, has diminished in size, and there is no trouble since his marriage Remains well after one year's observation

No 169—Prostatitis Multiple and Impassable Strictures Retention and Spasm—J B S, æt 50, New York City, married Has been troubled with strictures for 6 years, has been treated by dilatation, once urethrotomy was performed, all without relief Has no urethral discharge, but catarrh of the bladder with violent contraction, at times retention The stream is very small, most of the time the urine dribbles away by overflow of an over distended bladder About 20 years ago had a series of attacks of gonorrhœa, after one there was continuous discharge for 1 year For the last 3 weeks his family physician has tried daily to introduce instruments into his urethra, sometimes manipulating for 2 hours at a time At last was unable to pass any instrument, offered patient an introduction to a surgeon, saying perineal section was the only means of relief In this state patient came to me, Oct 30, 1885, in great agony, with spasm of the bladder and complete retention

On examination with *bougie à boule* found strictures everywhere throughout the urethra, there were 6 distinct strictures from 1½ to 8 in from meatus Up to 5 in a No 17 French could be introduced, but beyond that, the strictures were impassable An other complication was an enlarged prostate, which pressed at the neck of the bladder against the urethra and prevented the outlet of urine

Electrolysis with the combination electrode catheter It was very difficult to introduce any instrument into his irritable urethra, which had been wounded by former injudicious manipulations, and bled at touch However, I succeeded with a filiform guide, which passed into the bladder An electrode combination catheter, No 29 French, tunnelled at the end, was then passed over the guide by electrolysis In 12 minutes the electrode had passed all strictures and entered the bladder An electric current of 3½ milliampères was used The guide was withdrawn, as well as the silver stiletto, and a quart of urine drawn off The spasm of the bladder ceased, and patient felt comfortable at once

Nov 1 Has micturated in a small stream voluntarily about every 3 hours, has no pain, soreness is less

Nov 2 Came to the office nervous and in distress, with spasm of the bladder, fearing another attack of retention The lower strictures are very tight, and will scarcely admit a filiform guide, which is frequently arrested by the lacunæ The whole urethra is tender and sore from former injudicious catheterization by the family physician Electrolysis Tunnelled electrode, No 11 French, egg shaped, over a filiform guide, 3 milliampères for 15 minutes passed all strictures with difficulty The treatment by electrolysis was continued for 3½ months, in which, altogether, 9 séances were held, and the strictures enlarged from 0 to No 25 French It was difficult to manage the case, as the cystitis, enlarged prostate and mutilated urethra made complications which needed extra care and separate treatment, at the same time The cicatrix left from the former urethrotomy was more difficult of absorption than any other of the other ordinary strictures Hæmorrhagic points of the urethra and the enlarged prostate were successfully treated with galvano cautery At this time the patient felt so well that he neglected treatment and made a trip South while he was not considered cured, and was warned not to neglect treatment

March, 1887 During a year's absence patient has felt well, and not suffered at all, and appears now from fear of a relapse Examination showed that some places in the urethra were sore, bleeding at touch, and liable to contract As patient had not been dismissed as cured, such condition was anticipated For several months he was treated again by electrolysis and galvano cautery, is so much improved that a sound No 25 passed easily into the bladder He is considered well, but remains under observation

No 177 —Stricture, Enlarged Prostate, Cystitis, Retention —T D , æt. 56, N Y , married Jan 22, 1886, was sent to me by Dr C S Wood Has had stricture for 26 years In 1860 a doctor caused him agonizing pains by using a strong injection, which appears to be the cause of his stricture Has been treated by dilatation off and on Of late has had spasm of the bladder and distension, so that he could not void urine voluntarily The urine dribbled away by overflow and most of the time he had to use a catheter The stricture closed up more and more till he could neither pass a catheter or void urine On examination three strictures were found at 3½, 6½ and 7½ in respectively, from the meatus The last two were impassable With difficulty a filiform guide was introduced Electrolysis, No 9 French, tunnelled, with catheter combination over guide passed all strictures

Jan 27 Electrolysis was repeated with a No 11 French tunnelled over a filiform guide (5 milliampères 10 minutes) In the evening came to the house in distress, with retention, was not able to pass water A syphon arrangement was made and urine drawn off drop by drop In this manner 1½ pints of muddy urine evacuated, which was putrid and loaded with pus

Jan 28 At 10 A M had not been able to pass any water The bladder had been distended to such an extent that it had lost its contractile power A small catheter was passed, and assisting with syphon at intervals, during 1½ hours 53 ounces of urine were emptied from the bladder This urine was thick, putrid with solid masses of disorganized stinking pus At 6 P M bladder will not act, flexible catheter will not pass A small silver catheter was introduced on a guide and 24 ounces of water drawn off, which had a better color, was clearer and contained little pus

Jan 29 Faradization of bladder, after which he could pass water While a guide was in the urethra 20 ounces passed Bladder washed out, the urine is improved

Jan 30 Micturition voluntarily

Feb 1 Electrolysis No 14 French, egg-shaped, tunnelled over guide, 4 milliampères 7 minutes

Feb 3 Bladder washed out and dilated

Feb 5 Electrolysis No 17 French, egg shaped bulb, tunnelled over guide, after which he passed a better stream The treatment by electrolysis and washing out the bladder was continued in the same manner till July Then a No 23 French sound passed easily into the bladder and patient felt well, having regained full power of his bladder After 1 year patient is entirely well, and objects to further treatment as he is perfectly satisfied with his present condition

Group III Strictures caused by traumatisation, some accompanied by perineal fistula No 140 Dr W T , æt 39, New York, April 1, 1884 Has had urethritis, and a stricture of 9 years standing By an accident, a ragged instrument cut the urethra in the prostatic portion, partly in the neck of the bladder This was not healed and a constant source of annoyance, causing hæmorrhage at intervals, particularly on passing an instrument Part of this cut has cicatrized and caused the stricture, the other part remaining as a granulating ulcer Electrolysis was used by an excellent practitioner, who failed because he used too strong a current, and handled the instruments carelessly Examination revealed unevenness caused by the traumatisation on the lower side of the urethra, in its depending portion, left side Electrolysis was used with a No 25 French egg shaped bulb, negative pole against the stricture, 5 milliampères for 12 minutes, with decidedly good result During 6 months of very irregular attendance 10 seances were held with electrolysis The electrode gradually enlarging until a No 32 French passed easily into the bladder without causing any pain or hæmorrhage No 30 would have been large enough, but No 32 was used at the special wish of the patient

1887 The patient has remained well

No 179 —Stricture, Perineal fistulæ —B U H , æt 35, New London, married Had a stricture for last 6 years, occasioned by an accident to the perineum A urethral abscess behind the scrotum appeared, which in time broke and established three separate fistulæ, through which matter and urine passed Had been treated by different physicians Urethrotomy had been used without benefit The strictures grew smaller, so that voluntary micturition was difficult and retention prevailed The bladder was distended and the urine dribbled away from overflow The constant dribbling of urine and discharge from fistulous openings made it necessary to wear a urinal Patient failed in every way, and was not able to attend to any business Then he applied to Dr A W Nelson, a well known, conscientious surgeon of New London, who referred him to my friend Dr A T Douglas, of the same place, to be treated by electrolysis

Jan , 1886 From this time the patient was treated by Dr Douglas and myself There were two distinct strictures at 3½ and 6½ in respectively, from the meatus, one of which was so small that no instrument would pass The urethra was irritable, the walls indurated, the fistulæ in the perineum running, and the perineum itself changed to an unrecognizable mass of infiltrated tissues Dr Douglas succeeded very well with the electrolytic treatment and enlarged the strictures in a few séances

Feb 4 I operated in New London with electrolysis in the presence of Drs Douglas, Nelson, Bramman and Stanton The strictures were passed with a No 25 French, egg-shaped bulb Soon afterwards the patient felt well and passed voluntarily a good stream of urine

Feb 9 Dr Douglas wrote to me "H was here about half an hour ago, and says he has never passed his water so freely as he did Friday and Saturday" Subsequent applications of electrolysis made him a healthy urethra of No 28 size The fistulæ all healed spontaneously as soon as the strictures were enlarged

Feb 18, 1887 A reexamination showed that no contractions had taken place A No 28 passed easily into the bladder and the patient has enjoyed perfect health and attended to his business

No 183 —Four Strictures, Traumatism, Rupture of the Urethra —H K, æt 42, married, New York City Has had strictures for 18 years, caused by former urethritis and accidents Has also suffered from cystitis, received a kick in the perineum by an accident Once he used a sound so forcibly that he ruptured the urethra Has been treated off and on, mostly by gradual dilatation, without much benefit He can tolerate the use of instruments well

April 9, 1886 Examination *Bougie a boule* meets slight indurations and thickenings of the walls of the urethra, and is arrested at 5½ in Sound No 12 will not pass this stricture A filiform guide passes easily into the bladder, over which a tunnelled sound No 9 ran tightly There were four strictures at 4, 5¼, 6¼, and 7¼ in from the meatus

April 15 Electrolysis, filiform guide, over which a tunnelled electrode No 11 French, egg shaped was used, 4 milliampères for 8 minutes It passed through all strictures, the hard ring stricture at 6½ in was overcome by slow manipulations and lowering the curve of the instrument Dr Lawson was present

For 4 months the electrolysis was continued in séances of about 9 days' intervals The sizes of the electrodes were gradually increased each séance in the following order No 14, 27, 18, 20, 23, 25, to 28 Patient was well and at last accounts, was, in 1887, in Arkansas

In all cases which were complicated with perineal fistulæ, it is a fact that they healed without any special treatment as soon as the strictures were enlarged and a urethral canal established

Group IV Strictures impassable —This group has, in a measure, been anticipated, as it is complication concomitant with other troubles in former cases A stricture is called impassable when the smallest regular instrument cannot be introduced through the obstruction of the urethra In these cases the urine may dribble away, and a filiform guide may be introduced

No 138 —This is a case belonging partly to the last group, as it was of traumatic origin, besides being impassable A N, æt 48, New York City, has had a stricture for 41 years, occasioned when a boy 7 years old by falling from a hay loft astraddle on an oat bin The strictures were multiplied by urethritis contracted in later life

March, 1884 Came under my observation The urethral canal was so small that the *bougie à boule* or any other regular instrument would not pass further than 2½ in from the meatus After some manipulations a filiform guide entered Electrolysis with a No 9 French, conical end, tunnelled electrode was used over the guide A current of 5 milliampères for 9 minutes was successful, and passed two strictures and the spasm into the bladder There were two strictures at 2½ and 3 in respectively from the meatus

After two more successful séances of electrolysis a No 14 French passed the strictures, when the patient disappeared

Sept 5, 1886 Nearly 2½ years later the patient reappears, with the following story While he was perfectly satisfied with the progress made by electrolysis, he was persuaded to have a cutting operation He submitted to urethretomy Six weeks after a sound No 30 French passed easily, and he was declared cured 1 year afterwards an eminent surgeon had to make an official report, and he found that the patient had two tight strictures at 2½ and 3 in from the meatus, proving that urethretomy had been a decided failure, and the gentleman lost his position in consequence Since then, the strictures have contracted more and the patient comes to day frightened and begging for electrolysis again The strictures were found to be contracted to about No 18 French, and the cicatrices caused by the after effects of the cutting, so tough that they were calcarious, and yielded very slowly to absorption The electric séances were recommenced in intervals, and the calibre of the urethra gradually enlarged to a No 28 French, size The patient is now well

May, 1887, was reexamined with a No 28, which proves that no relapse has taken place

No 168 —Impassable Stricture, Retention —P E, æt 38, New York City, widower Oct 11, 1885 Has had gonorrhœa in former years The stricture was marked two years ago, when the stream became gradually smaller and made micturition very troublesome At present he cannot pass water at all, and is relieved only by dribblings from the overflow of a distended bladder No bougie will pass the urethra and the patient is in great distress, having positive retention A filiform guide made its way with the greatest difficulty, there is really no urethra Electrolysis Positive electrode was held in the palm of his hand, the negative pole, a tunnelled electrode with a conical end, No 9 French size, was passed over the filiform guide, and advanced very slowly but steadily, and finally passed into the bladder The urine was drawn off, 4 milliampères were used for 6 minutes In this case it was impossible to state the number of strictures as the whole urethra was a mass of strictures

Oct 25 Electrolysis The filiform guide entered after some time spent in manipulations No 11 French, tunnelled, conical end was very tight, and advanced very slowly The worst point of the stricture is at 6½ in 10 minutes were occupied with a current of 5 milliampères

Nov 2 Electrolysis No 18 French, egg-shaped bulb, 3½ milliampères for 11 minutes

Nov 10 Electrolysis No 18 French, egg-shaped, no guide

Nov 18 Electrolysis No 20 French, egg-shaped, no guide

Nov 30 Electrolysis No 23 French, egg shaped, no guide

Dec 4 Electrolysis No 25 French, egg-shaped, no guide

Nov 1886, 1 year after, was reexamined with a sound No 25

1887 Heard from, is well

Group V—Strictures which are complicated with constitutional diseases, as Gout, Rheumatism, Pyelitis, Syphilis, etc—Typical cases we find in *Nos 114, 126, 154 and 185* of our statistics It is scarcely necessary to give these cases in detail The point is to call attention to the fact, that such diseases aggravate the strictures to the degree of acute inflammation These inflammations must be subdued before electrolysis is used Such intercurrent diseases must be treated according to their nature and indications

Group VI—Regular cases of Stricture, (single or multiple)—These are typical cases as they occur most frequently, and appear oftenest before the general practitioner One case will suffice to show, as a general rule, the treatment

Case No 148—J W, æt 32, married, New York city July 28, 1884 Twelve years ago contracted venereal, had urethritis, chanchroids and bubo, the latter was lanced Two years ago had another urethritis, which ran into gleet, and is still present Every morning the meatus sticks together with a film, which when broken, lets out two drops which are almost transparent white and sticky The stream of water has grown smaller, and is now very thin, twisted and without force Since last year the testicles are swollen

Examination—Testicles hang down low, simulating a degree of degeneration, of tuberculosis Meatus is small *Bougie a boule* meets with indurated walls throughout the urethra, the touch transmitted by the instrument is like parchment, and in a few spots cartilaginous The course of the urethra is tortuous Four strictures are found, in the following places 1st stricture is near the meatus, 2d stricture is 4 inches from the meatus, 3d stricture is 5 inches from the meatus, 4th stricture is 6¼ inches from the meatus

August 3 A filiform guide met with obstacles everywhere, but was finally introduced into the bladder *Electrolysis* Positive sponge electrode is held by patient and pressed in the palm of his hand The negative pole is a No 14 French electrode, egg-shaped bulb, tunnelled, to run over the guide in the urethra The current applied was 4 milliampères for 5 minutes The electrode passed slowly through all the strictures into the bladder Patient is weak, run down constitutionally and nervous

August 4 Feels better, has voided urine easier

August 10 Electrolysis, over guide with tunnelled electrode No 17 French, egg-shaped bulb, 4½ milliampéres, 11 minutes, passed easily through all strictures While the instrument was in the bladder, some spasm took place

August 17 Electrolysis, No 17 French, egg-shaped, without a guide advanced easily

August 24 Electrolysis, No 20 French, passed all strictures 5 milliampères, 6 minutes

August 31 Meatus is very small, so that it will not admit of a larger size than No 20

Sept 21 Electrolysis The meatus is enlarged by an electrical stretcher, which worked so well that a No 28 could be introduced

Sept 28 and Oct 5 The electrolysis with the meatus stretcher was repeated

Oct 12 He is better in every way Has no gleety discharge Bougie cannot detect any stricture Is well

Oct, 1885 Reexamined with a No 28 No relapse Well

68 West 36th St, New York

UNDUE INFLUENCE IN ITS RELATIONS TO MEDICAL JURISPRUDENCE

BY AMOS G HULL,
OF THE NEW YORK BAR

Read in the Section of Medical Jurisprudence, at the Thirty-Eighth Annual Meeting of the American Medical Association, June, 1887

If it had been determined that a paper should be read on the most nebulous subject within the realm of Medical Jurisprudence, perhaps none could have been selected more obscure and undefined, than the one on which I am about to speak

Undue influence in its medical and legal relations is my theme This topic has been rendered cloudy by the manner in which the subject has been treated by lawyers and judges, and doctors and authors It has not been relieved from the clouds of obscurity which surround it, by the learning and research of the judiciary of two continents There has seemed to be a hesitancy on the part of the bar to give it any settled or uniform definition That hesitancy has seemed to grow out of the difficulty of finding cases on this subject with uniform characteristics It is the absence, or imperfection of correct definitions, which tends to trip the feet of students and philosophers all along their journey through life while in search for truth Whoever shall give a *perfect* definition to Medicine or Law, to Science or its attributes, or to Nature, that Omnipresent Power, that surrounds us all, will be wiser than any being that has yet been born

Very few of the elementary writers have attempted to define this subject There are many difficulties that will confront any one who attempts to give it a satisfactory definition The judges who have had occasion to adjudicate upon it, generally have discussed the facts in each case as they arose, and when finding the subject matter tainted with undue influence, have pronounced judgment against it on the ground of fraud *and* undue influence Such a judgment is a misnomer—if it is an incorrect use of terms It is as absurd to say that an instrument is void for fraud and undue influence, as it would be to say that it is void by reason of a *fraudulent fraud*

Undue influence has its origin in fraud It is in and of itself a fraud But this infirmity of man, wherein fraud is born, with which courts have so much to do, has in its ramifications an extensive nomenclature It frequently amounts to crime, and is punished as such under different names

question And if a gift or contract made in favor of him who holds the position of influence is challenged or impeached by him who is subject to that influence, the courts of equity cast on the former the *onus probandi* of proving that the transaction was fairly conducted as if between strangers, that the weaker was not unduly impressed by the natural influence of the stronger, or the inexperienced overreached by him of more mature intelligence" See the very interesting case of Haydock vs Haydock, 33 New Jersey Equity, where an excellent definition of undue influence is given

In the case of gifts or other transactions *inter vivos* among the above named class of persons, it is considered by courts of equity that the natural influence which such relations as those in question involve, exerted by those who possess it to gain a benefit for themselves, is an undue influence

From the foregoing definitions and illustrations we may deduce the following rules In order to set aside the will or deed, or contract of a person, by reason of undue influence, we must have

1 A subject whose mind is impaired by disease or infirmity

2 There must be fraudulent persuasion or irresistible importunity

3 The subject must be fraudulently induced to do that which he would not do if left free and in his normal condition

When these concur we have *undue influence*, but when a man in the free and healthy possession of his powers is induced by trick, deceit, cunning or circumventions to execute a deed, a will, or make a contract, unjust to himself and others, such cases are denominated *actual frauds*, and redress should be given in the courts under that characterization With these general principles and definitions before us, we become interested in the examination of actual cases which may tend to their illustration

It was my purpose at the commencement of the preparation of this paper, to give some of the prominent facts relating to a large number of leading cases in this country and in England The limits prescribed to the reading of a paper here, will only give me time to briefly allude to a few in this country in addition to those already cited

Higgins vs Higgins is an interesting case It was tried in the City of New York in the Supreme Court, and was reported at length in the papers at the time It was never taken to the Court of Appeals, and hence does not appear in the reports of that Court The plaintiff, George Higgins, had been for over 25 years the chief bookkeeper, cashier, and confidant of the eminent merchant, the late A T Stewart He had a large salary, and by his frugal habits, economy and careful investments, was accumulating a handsome property, when he met at a boarding house a strange woman—a gay, gushing "grass widow," who induced him to marry her, without making any inquiry into her antecedants They lived comparatively happy for a year or two, when by reason of close confinement to his desk, for 16 hours out of 24, under severe mental strain, while cohabiting with such a woman his health began to fail He was treated for impotency and began to show premonitory symptoms of multiple sclerosis As his will power began to fail him, his wife commenced her importunities to induce him to transfer all his property to her In a short time that was accomplished His health failed to such an extent that soon after Mr Stewart's death Judge Hilton, Stewart's successor, retired him from duty, on a salary in the nature of a pension, for a time

Mr Stewart in his will had made a bequest to Higgins of $10,000, using these words in the will to wit that the money was given "in remembrance for long and faithful service" The legacy was paid to Higgins immediately after the proof of Mr Stewart's will, and in less than three days his wife induced him to transfer the check for the ten thousand dollars to her, which she immediately invested in real estate, taking the deed in her own name She became so bold in her iniquity, that she conceived the idea of getting rid of her husband by putting him into an insane asylum She went to the authorities and represented that her husband was a pauper and was insane, and by the help of a wicked pliable doctor placed him in the pauper department of the violently insane, at Bellevue Hospital, where he remained among the worst of the lunatics for two or three days The authorities finding him a broken down, harmless man, far from being a lunatic, set him at liberty She then conceived the idea of inducing him to commit suicide She told him that the money was all gone, and that she should put him into the Poor-house, besides she said that her friends had told her that Stewart's executor was about to arrest him for embezzlement That the best way for him to do was to take a large dose of morphine—that he would go to sleep and never wake up—that would be the end of him—that there was no hereafter The dread of being placed in a poor-house preyed upon him He had sense enough to disbelieve the story of his proposed arrest, but he went out and bought the morphine On his way home his Roman Catholic teachings as to the sin of suicide, came to his mind He refused to take the nap, which his kind wife had advised She then told him that as he had an acquaintance in Chicago, she would pay his fare to that city

She took him to the depot, bought a ticket, fastened it to him as a tag, as one would to a dog, for transportation She put two dollars in his pocket to pay his expenses on the way He arrived in Chicago and found kind friends, by whom he was so kindly and tenderly nursed that in a few weeks he was able to return to New York in much better health He at once commenced a suit against his wife to recover his property, on the ground of circumvention and undue influence On the trial, which lasted about seven days, it was proven that at the time he was married he was led into the snare of marrying a woman who had a husband living, that she had been engaged in keeping a policy shop, which fact had been adroitly concealed from him

Expert alienists were put upon the stand to show the mental condition of Higgins at the time he made the transfer of his property to his wife Several medical witnesses, among them one of our leading

alienists, an author of a recognized treatise on insanity and known to all of you as an original investigator in the anatomy and pathology of the nervous system, who to day honors us with his presence, testified to the mental condition of the plaintiff, demonstrating that his infirmities were such, and his mental impairment so great, that he could very easily be made a prey of undue influence The court made a decree restoring all the property in question to the plaintiff, on the ground that it had been fraudulently obtained from him by *undue influence*

An interesting case was tried last year in Chenango County, N Y The will and codicils thereto of Asa R Foster were contested In every case that I have found in this country, except this, the party exercising the undue influence has had some pecuniary interest or gain to accomplish as the reward for his iniquity But in this case he would not be benefited in the least by the change he was seeking to make in the decedent's will He had a spite against some of the relatives of the testator who had been provided for in the will, and he set about the work of having a new will made, and having the persons whom he disliked deprived of any part of the estate, merely to gratify his malice He accomplished his purpose, but the will was set aside on the ground of undue influence James W Glover, Esq , of Oxford, N Y , was the counsel for the contestants in the case

Perhaps the Hancock case, reported in 22 Hun , 38, contains as many interesting points on the subject of undue influence as any other reported case For instances of adroit cunning and audacious villainy it transcends any case within the history of the jurisprudence of this country It cannot be analyzed in one short hour It occupied over four years in taking testimony, at intervals, in the Probate Court I can only call attention briefly to a small number of its peculiar features

For the better understanding of the case a biographical sketch of decedent will be proper Hancock was born in England about 84 years ago He left no widow or children In person he was about 5 feet 8 inches in height, of heavy form, rather large neck, and florid complexion He was a moral and very polite man, but of an irritable and impetuous temper, hasty in his conclusions, and sometimes uncharitable in his judgment of men He was very upright in his dealings, full of sympathy for the poor and oppressed, and abounding in benevolence In 1850 he was engaged in the hosiery business in the city of New York in company with Mr C M Carpenter He continued in business for 19 years, and amassed a fortune of over $200,000 During all these years, and until he became demented, a very warm personal attachment existed between himself and Mr Carpenter, so much so that he never engaged in any important business transaction without first consulting him He frequently said that he was under more obligation to Mr Carpenter for his fortune than any other person living In 1869 he made a will, appointing Mr Carpenter one of his executors, making a large bequest to him and his family, and vesting in him important trusts

While he was accumulating his fortune he made his home with Mrs Thatcher, a kind, genial, and most estimable widow lady, who was then keeping house in Brooklyn She having removed to Orange, N J , he went there to reside with her, and to make that his home, her son, until his premature death, being one of his favorite employés, her daughters nursing and watching him in his sickness with filial care and tenderness, and their mother sparing neither care, nor time, nor toil nor expense, in making him such a home as his circumstances would suggest while in active business pursuits, and such an asylum as his infirmities seemed to require in his declining years He spoke of her home as his home, and of her daughters with a tenderness akin to parental affection That lady and her daughters he liberally provided for in a will of 1869, and another will of 1874 He increased the amount to Mrs Thatcher in the will of 1874 He had a nephew whom he had educated, who had entered one of the learned professions That nephew had been abundantly remembered in the will of 1869 and in a will of 1873 He was bequeathed a large sum in the will of 1874, and was made an executor in the will of 1874

Intermediate the date of the will of 1869 and the will of January, 1874, a number of papers had been drawn at the request of Hancock, designed to be executed by him as his will, in all of which he had made large legacies to Mr Carpenter, Mrs Thatcher and her daughters, and to his nephew Whether those papers were ever executed does not appear The fact of his friendly regard for all these persons does appear, and continued to be manifested until he became the victim of the frauds hereafter mentioned His plan for the distribution of his estate was to bestow about one half upon his kindred, and divide the other half between his personal friends and benevolent societies

His mind and memory began to fail him soon after the year 1869 In 1874 he was informed by an eminent physician, Dr Pierson, that a slow paralysis was coming upon him In February, 1874, he had a severe stroke of paralysis From that time until his death his mental powers failed to such an extent that at the time the two codicils, dated April 14, 1874, and July 1, 1874, were executed, his testamentary capacity was all gone The second and third alleged codicils to his will were contested on the ground of fraud, and also undue influence

In April, 1874, he went to the house of his brother-in-law, at Nanuet, to visit his friends, with the view of returning to his home in Orange His illness increased He was induced to remain at Nanuet, where he languished during the summer, and on the 12th day of September, died How, during that fatal summer, the whole purposes of his life became apparently changed, how the proponent, for whom through life he manifested the greatest aversion, came to be appointed his executor in place of his friend, how all the bequests to Mrs Thatcher and her daughters, and to Mr Carpenter, and to his nephew, and to most of the charities, came to be revoked, and how his life-long friendship for Mr Carpenter and his nephew were turned to hate, and why it was that frauds and

impositions were practiced upon that dying man to such an extent as to deprive him of the ability to make a free and valid disposition of his estate, and why alleged codicils to his will were absolutely void, it becomes interesting to consider

The line of attack upon the codicils consisted principally of four divisions.

1 To prove his failure of memory

2. To show the physical infirmities of the decedent

3 The duress, restraint, and deception to which he was subjected

4 The actual frauds that were practiced upon him

1 There were 16 witnesses placed on the stand by the contestants, most of whom had long been acquainted with the decedent, and had many business transactions with him, to testify respecting his memory They described 19 distinct instances showing defect of mind and memory, aside from the testimony given by the experts He was proved to be unable to recall places, or remember the locality of his recent familiar resorts Having bought clothing he would be unable to say the next day how he came by it He would deny that it belonged to him Having burned the draft of one of his wills he forgot what became of it, and accused one of his friends of having carried it out of the country

Having made a codicil to his last will disinheriting a beloved friend, he was asked if such was the fact, and he stoutly denied it, and claimed that the friend was a legatee to a large amount He would furnish his lawyer with a draft of a will, in his own handwriting, and come the next day with another, and when told that he had furnished one the day before, he would deny it, and on being shown the paper which he had left, would say "Oh, yes! I had forgotten all about it" This happened on as many as ten or twelve occasions

He was unable to recall the names of the beneficiaries under his often prepared but unexecuted wills He was unable to recall to mind the condition of his estate These are only a few specimens of his failure of memory

2 His physical infirmities were proven to consist of paralysis under the designation of hemiplegia, also an aggravated form of diabetes mellitus and senile dementia

Dr Pierson, of New Jersey, who had been his medical attendant, made a thorough diagnosis of his case His infirmities were aggravated by the conduct of the proponents during the incubation of the iniquity which resulted in the codicils They gave him beer in the morning, wine at noon, and brandy at night Dr Pierson testified that the mind of the decedent was so impaired as to be unfit to make a valid will Dr Charles Corey, who has had much to do with mental disease, testified to the same, also Dr Dougherty, of New Jersey

3 The testimony was conclusive that he was restrained by proponents to remain with them away from his home, his confidential friends, his nurses, and his trusted advisers—where he had a right to be to prepare for the solemn scenes of his approaching dissolution

4 The actual frauds that were practiced may be grouped together as follows

First They conceived the plan of making him believe that the will of January, 1874, was void for informality in its execution They saw that before anything was to be said against any bequests, or against the character of any of the legatees, in order that they might not be met with the argument that it was too late now—that the will had been made, no changes could now be made—it would become necessary to get rid of the will of 1874, either by a new one or by codicils thereto, when that was out of the way, then an open field would lie before them to make out such a will as would suit themselves, hence, they commenced fraud number one, which consisted in impressing on his weak mind the adroit, well-planned, but transparent lie, that the will of January, 1874, was defective because the subscribing witnesses had not put down their residences All lawyers know, most laymen know, that such omission does not in any degree invalidate the will

The evidence was that the proponents had talked over the pretended defect It is apparent that they had taken it to some lawyer, and he had told them that the omission did not invalidate the will, but they resolved to use the discovery as a "good enough Morgan," and hence they persisted in playing the fraud upon him by telling him that the will was not properly executed He often said, "I don't want to make any changes in my will" The proponent gives one of his lucid versions to the matter

Question Did you ever state to the testator, at any time, that the places of the residences of the different witnesses were not stated in the will, or were not known, and that such omission might prove embarrassing in the future, or words to that effect?

Answer I can't say for certain I might possibly have said it

Q Did you ever hear your wife, or her sister, say to the testator anything like that?

A I think I heard my sister in-law say to the testator that the place of their residence was not in the will

Q When did you hear her say that?

A I think it was some time in October, 1874 No, it was a month or two before he died It was in July, 1874 No, I recollect now, it was in September—I remember the circumstance

Q What time?

A It was the evening of the day of the funeral

This fraud was practiced on the dying man at the very time when he was protesting that he wanted to make no changes in his will But having yielded to fears excited that his will was void by reason of the omission of the witnesses to state their residences, aroused by the fear of dying intestate, he yields that point, and consents either to consent to make a new will, or make codicils, or have the lawyer come and fix it so that it would be legal

Having gained the first point, and overcome his express desire "not to make any changes," the remaining task to accomplish any and all other wicked purposes was easy Having by fraud made the decedent consent to make new codicils, the next step was to determine in the minds of the conspirators what changes should be made

Fraud No 2 consisted of the scheme to get rid of Mr Carpenter That was to be brought about by using the scissors on the letter of the nephew, and parading the words before the remnants of the intellect of that slow dying paralytic, "Carpenter is a villain" "Carpenter's no man to be an executor" "Your own dear nephew says he is a villain, and has undoubted proof" The nephew had written his uncle a letter which would have been damaging to the proponents, if put in evidence, but it contained the words "Carpenter is a villain" "He is no man to be an executor" The proponents' counsel were so unwise as to cut out those words, and offer them in evidence, detached from the letter The truth was that this pious nephew (a sort of a preacher) was anxious to have Carpenter discarded as executor in order that he might have the place himself It turned out to be a boomerang, to trouble the hypocrite It became necessary to say nothing against the nephew while they were manipulating matters against Carpenter, because they were using the nephew as a witness against Carpenter But as soon as they deemed the mind of the decedent sufficiently poisoned against Carpenter, they then opened against the nephew himself

Fraud No 3, which consisted of the cut leaves which the nephew had attempted to explain The decedent, no doubt to get rid of their importunities while in his weak state of mind said, "Yes, strike out Alex , if he would do all this he must be a rascal and a villain" And yet in his lucid intervals, it is evident that he did not know that he had cut his nephew out of his will The next step in this drama of fraud was to get rid of Mrs Thatcher and her daughter and the little orphan children at Orange So firmly were the testator's affections placed upon this lady and her family, that they dared not open their schemes against her until May or June, nor until that enervating disease which they saw was rapidly carrying their victim to the tomb had made him an easy prey to their designs

Fraud No 4 consisted in creating the delusion that Mrs Thatcher had been robbing him This was done by the proponent, with the aid of others in his family, as the evidence shows, substantially as follows

After discussing what had been done for Mrs Thatcher, proponent brings in the books and says "Why, John, I can't make out anything from these books They are all wrong They have had them at Mrs Thatcher's They have fixed them to suit themselves Why, you have been robbed!" The decedent did not stop to see what sort of a bookkeeper was addressing him No wonder that the proponent could not make out anything from the books It would have been as appropriate to employ him in calculating an eclipse of the sun as to ask him to determine correct results from his examination of a set of account books He knew that Hancock had made his home at Mrs Thatcher's for nearly 15 years He knew that a man of Hancock's wealth could well afford to pay for such care and nursing as he enjoyed at least $2,000 per year—a sum equal to $30,000 He knew that all the money that Mrs Thatcher had received was nothing like that sum, and yet he attempted to impress upon the mind of the decedent that he had been robbed by Mrs Thatcher But they had other arrows in their quiver Maria comes to the front She tells her brother that Mrs Thatcher had tried to marry him, and tried to seduce him

By what process the mind of the decedent was filled with the delusion that his friends at Orange intended to poison him, is known to none but Omniscience and the proponent's family But the law has wisely and humanely stepped in and said that the contestants are not bound to give the process by which the delusion was created It is enough to show the existence of the delusion The Court of Appeals said in the case of Tyler vs Gardiner, hereinbefore cited (35 N Y, 594) "It is not to be supposed that fraud and undue influence are ordinarily susceptible of direct proof" This very delusion in reference to fear of poison, while it was used as an influence to deprive Mrs Thatcher of any share in the estate, is a powerful argument that the decedent was insane

In Seaman's Friend Society vs Hopper (33 N Y, 624), the law is laid down as follows "If a person persistently believes supposed facts which have no real existence, except in his perverted imagination, and against all evidence and probability, and conducts himself, however logically, upon the assumption of their existence, he is, so far as they are concerned, under a marked delusion, and delusion in that sense is insanity"

Having got rid of Mrs Thatcher and the other legatees at Orange it becomes an easy matter to dispose of the little innocents of the orphan asylum at Orange The conduct of the proponents during the last days of the testator's life furnishes evidence of the strongest character that they were haunted by spectres of their frauds in procuring the last two codicils, and were determined to obtain possession of every dollar of his property without regard to wills or codicils, and thereby prevent any investigation which would expose their infamy To accomplish this the proponents employed a person calling himself a lawyer to prepare a power of attorney containing a transfer of all the property of the decedent to the persons who had procured the codicils to be made, to which they procured the signature of the decedent to be affixed while in a moribund condition, which they took to his bankers and demanded the decedent's money The papers being informal the bankers declined to pay until papers could be properly authenticated They were taken back to a notary for correction But before they could again reach the bank, the testator was dead

The two codicils were set aside by the Probate Judge on the ground of undue influence alone His decree was affirmed at the General Term of the Supreme Court and again by the Court of Appeals The case is reported in the Supreme Court in 22 Hun 40 The opinion of the Surrogate was very learned, lengthy and elaborate, while it was followed in the higher courts, yet it was not *republished* in the appellate courts

Permit, in conclusion, a single reflection upon the moral aspect of this singular case

All experience shows, all history proves, from the earliest moment of recorded time, that one of the brightest attributes of human nature is that which prompts respect for the solemn scenes which surround the departure of a human soul Among all civilized people, particularly among Christian and Hebrew societies, and even among pagan nations in modern times, when the wings of the Angel of Death begin to cast their dark shadow upon a household all business is laid aside, passion is hushed, avarice is mute, footsteps are muffled, friends communicate in whispers, silence surrounds the solemn scene If the ties of blood or affection are about to be severed, tears of affection bedew our cheeks while aspirations of prayer escape our lips What do we find in this case? No sooner is the alarm given that the dread summons is approaching, than fleet horses are harnessed, a huge document is prepared bearing great seals The pretended executor of the estate of the dying man, and his unwilling beneficiary to the amount of thousands of dollars, procures a dual signature to a document giving the substantial control of every dollar of his estate to himself, and instead of standing by the bedside of his friend to show sympathy and comfort, he is seen, armed with his commission, flying back and forth to perfect his documents for two full days between Spring Valley and New York, with all the speed which nimble-footed horses and lightning express trains could afford, until we find him knocking at the door of the bankers of the decedent to seize his last dollar at the very moment when the immortal soul of that benefactor was taking its departure to realms unknown Seldom do the annals of avarice show a more depraved exhibition of human nature

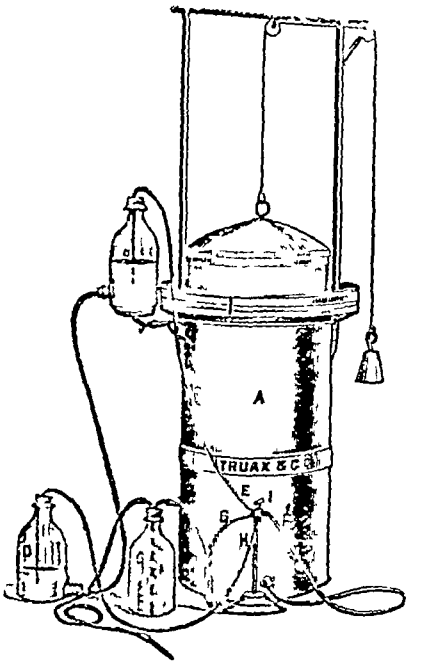
A NEW FORM OF APPARATUS FOR ADMINISTERING GASEOUS ENEMATA

Read in the Section on Medicine, Materia Medica and Therapeutics, at the Thirty Eighth Annual Meeting of the American Medical Association, June 7, 1887

BY J H KELLOGG, M D,

OF BATTLE CREEK, MICH

The phenomenal interest which has been manifested in the so called Bergeon method of treating pulmonary consumption by means of gaseous enemata, which is by no means confined to the profession, but has been largely shared by the general public, has created a most unprecedented demand for a new form of medical appliance designed to administer gaseous enemata Thus far this demand has been supplied by the simple and effective device of Dr Morel Many of those who have undertaken the extensive use of this apparatus, have experienced great annoyance by reason of the almost utter impossibility of totally excluding atmospheric air from the apparatus The inaccurate and tedious mode of using it, and the necessity for the handling of corrosive chemicals in the treatment of each individual case I encountered all these difficulties at once on beginning the trial of the new method, and was deeply impressed with the importance of designing some more exact and less inconvenient method of administering the treatment I soon designed and subsequently had constructed the simple apparatus which I herewith exhibit The special features of the apparatus consist



1 Of an ordinary gasometer similar to that used in the Waldenberg apparatus for the treatment of pulmonary diseases

2 Of 2 three-necked Wolffe's bottles The 2 bottles are connected by means of glass and rubber tubes The 2 wash bottles are connected thus The perforated rubber stopper of the middle neck of each bottle has fitted into it a glass tube of sufficient length to reach to within a quarter of an inch of the bottom of the bottle These 2 tubes are connected by a continuous tube The corresponding side necks of the 2 bottles are connected by means of rubber tubes attached to glass tubes, in the perforated stoppers of just sufficient length to reach through the stopper Each end of each of these tubes is supplied with a stop-cock, such as is used with the ordinary fountain syringe Each tube is divided in the center, and each end connected to the opposing ends of a brass tube made in the form of a T To these T's are connected, on one side, a tube leading to the gasometer or storage tank, and on the other, a rubber tube leading to a wash bottle containing water charged with sulphuretted hydrogen, as in the apparatus now in use, from which the mixed gases are conveyed to the patient in the usual way

To prepare the apparatus for use we have only to fill the gasometer with carbon dioxide and one of the Wolffe bottles with water, and all is in readiness Pressure is obtained by elevating the Wolffe bottle which is filled with water, to a height of 12 to 20 inches After elevating the bottle, open the stop cock controlling the connection between the upper bottle and the tank, and also the stop-cock controlling

the connection between the lower bottle and the mixing bottle The water in the upper bottle now begins at once to syphon into the lower bottle, and in so doing displaces the contents of the lower bottle while the upper bottle fills with CO_2 from the tank When the upper bottle is empty, it is only necessary to close the 2 stop cocks, reverse the positions of the bottles, and open the opposite corresponding stop-cocks, and the same action will be repeated

This apparatus is, of course, designed especially for office use From what I have seen and learned of this method of treatment, I am inclined to believe that it is not by any means prudent to leave it in the hands of an ordinary nurse A thoroughly trained nurse could, undoubtedly, learn to administer the treatment as well as a physician, and might safely be trusted with the treatment in individual cases, as has been suggested, but educated nurses are not abundant, and certainly ordinary nurses, which are the only ones accessible in the majority of cases, except in a few of the larger cities, are wholly incompetent to administer a remedy which has produced death in lower animals in so small doses as 1 and ½ cubic inch I am also of the opinion that the treatment may be much more successfully carried out in an office practice than at the bedside, except, of course, in cases in which the patient is so reduced by disease as to be confined to his bed or his room For cases of the sort last mentioned, the apparatus which I am describing cannot, of course, replace the Morel apparatus But I am confident that for office use it will be found very much superior to the Morel apparatus in at least the following particulars

1 Convenience A storage tank may be employed of any size desired The tank which I here exhibit holds 10 gallons and cost less than $6 The carbon dioxide may be made at any convenient time and may be kept in a tank without deterioration for almost any length of time

Another element of convenience is found in the fact that when set going the apparatus is nearly automatic The Wolffe bottles which I show here hold about 1 litre each, and consequently it is necessary to make but 1 change in the apparatus for each litre of gas employed, whereas, in the old apparatus, the physician must keep his hand continually upon the injecting bulb and give undivided attention to the management of the apparatus By the employment of bottles holding 1 gallon or more, the number of attachments of the apparatus necessary in a given treatment may be proportionately lessened

2 Comfort of the patient There has been much complaint of pain caused by the employment of gaseous enemata, and patients have in numerous instances discontinued the treatment on this account, who might possibly have been benefited if the treatment could have been continued The chief cause of pain is generally believed to be the injection of air, or the too rapid administration of the gas It is almost impossible to effect the injection of small quantities of air in the use of the Morel apparatus It is impossible to roll the rubber bag so tight that every particle of air will be excluded, and the greatest care is necessary to prevent the inclusion of so great a quantity of air as to give the patient much discomfort It is also not at all easy to maintain a constant or uniform flow of gas by means of an injecting bulb, which is necessarily intermittent This new apparatus wholly obviates both of these difficulties When the storage tanks and the 3 bottles employed are once filled with carbon dioxide it is impossible for any air to find access to the apparatus or to be injected

In filling the storage tank, the total exclusion of air may be secured by simply sinking the inner cylinder until it is wholly filled with water, while the amount of air in the wash bottles is so small that a single filling and emptying of each of the Wolffe bottles is sufficient to exclude it entirely The advantage which this apparatus presents over the Morel apparatus in this particular is as great as that presented by the fountain syringe over the old-fashioned bulb or piston syringe In the employment of this apparatus, the flow of gas is necessarily uniform, or so nearly so that no perceptible change could possibly be observed by the patient The rate of flow may be regulated to a nicety by the elevation or lowering of the bottle which is filled with water Any degree of pressure desired may be obtained I have found an elevation of 20 inches to be sufficient to overcome the pressure of gas within the bowels The time required for the injection of a litre of gas by this apparatus, the acting bottle being raised to a height of 20 inches, is from 2 to 3 minutes, with an elevation of 10 inches, the action is considerably slower The flow of gases may be instantly stopped at any moment by the closure of either one of the 2 stop cocks, which are also open When the apparatus is in action, the patient or physician may stop the flow of gas instantly by simply depressing the conducting or injecting tubes

3 Accuracy In the employment of so powerful a toxic agent as sulphuretted hydrogen, it must be evident that the matter of precise and carefully regulated doses is just as important as in the employment of arsenic, strychnia, morphia, or other agents capable of producing poisonous as well as therapeutic effects

A rubber bag and an injecting bulb can hardly be regarded as the equivalent of the balance and the graduated burette, but by means of this apparatus, the amount of carbon dioxide injected may be measured with the greatest precision It is only necessary to graduate the Wolffe bottles by which the flow of gas is actuated, and by noticing the amount of liquid moved from one bottle to the other, the precise amount of gas which has been injected may be ascertained In this respect, the apparatus seems to leave nothing to be desired The liquid employed in the bottles is simply water colored with a little analine to render the movements of the liquid more perceptible As presented here, the apparatus is in a somewhat crude form as it is the first one which I have constructed, and a more complete apparatus which I had ordered made was not completed in time to present to this meeting Nevertheless, I have been employing it for some little time, and have been much pleased with its performance

One patient to whom the Morel apparatus invariably gave a very considerable amount of pain, notwithstanding the greatest care in its use, receives the treatment from this apparatus without the slightest discomfort

I think the use of Wolff's bottles with but 2 necks and an opening at the bottom of the bottle will be found more convenient than the form which I am now using, as it will obviate the use of the syphon which fails to operate without tilting the bottle after the column of water has been broken by allowing the upper bottle to become completely empty I have also devised a more convenient and substantial arrangement of the stop-cocks which I am having constructed

I do not offer this apparatus as one which must necessarily supplant the Morel apparatus, but for office use and for careful scientific investigation it offers the elements of convenience to the physician, comfort to the patient and accuracy of dosage, advantages which must be at once appreciated by those who are at all familiar with the administration of this new mode of treatment

AIDS IN THE PREVENTION OF FEVERS

Abstract of a Paper read before the Section on Practice of Medicine, Materia Medica and Physiology, at the Thirty-Eighth Annual Meeting of the American Medical Association, June, 1887

BY R W SLAY, M D,
OF TILCHER'S POINT, LA

In July, 1883, I was called to see L G L, who was suffering from a severe attack of remittent fever, from which he had not been free for the past seven days By a judicious course of treatment his fever was abated by noon next day I called in the evening, and as I was cautioning him to take sulphate of quinine as I directed, and that if, in spite of the treatment, the fever should return, he must take a fluid mixture I left to be taken during the existence of the fever, he said "Can't I take some of the fever mixture whether the fever is on me or not?" I thought a moment, and as I looked upon his pale, emaciated face and knew the disastrous effects a return of fever would have upon him, and as I hoped to be able to see him again in six or eight hours, I told him to take the mixture just as he had taken it while the fever was upon him He was also directed to keep up the quinine He had no return of fever for weeks

His query and the beneficial effects of the treatment pursued made me reflect on the use more often, as preventatives, of those remedies which we use during the pyrexia I have since tried this experiment in more than 100 cases, and in every case in which the test was properly carried out, there was no return of fever I desire that you should understand that I allude more particularly to intermittent malarial fevers, but I think the day is not distant when this form of treatment can be beneficially used in obstetric and surgical cases

In recapitulation of the causes of fever we will say they are

1 Arterial contraction
2 Accelerated action of heart
3 Increased tissue metamorphosis or oxidation
4 Probably a nervous influence causing an inhibitory influence on the usual changes in transformation

If we can give remedies which will prevent the three first known causes mentioned and the last theoretical cause, we can lessen or entirely prevent the occurrence of fever, in many cases We all use these remedies in the pyrexia, and we can advantageously use them in the preventive treatment We have such remedies in veratrum viride, aconite and similar remedies Veratrum viride acts upon the cardiac ganglia and the muscular substance of the heart, as is proved by paralyzing the pneumogastric with atropia, and it still affects these parts Aconite, we are told, acts in the same way I do not mean, in using these remedies, to prohibit the use of quinine, but that their proper use, as suggested, as *aids in the prevention of fevers* Use, for instance, for an adult not very weak, this prescription

℞ Tr veratri viridi (Norwood's) ♏xxxij
Tr aconiti ♏xxxij
Spts ætheris nitrosi ℥iv
Aquæ q s ad ℥j

M

S Give, in a half wineglass of water, a teaspoonful every 3 hours beginning 9 hours before the expected return of fever, and discontinue after fever time has passed

I desire to impress upon you that I wish to recommend medicine which will prevent the four causes which I have summed up as producing fever, rather than recommend any particular medicines, for we may have our own preference for several remedies, either of which may produce the same effect One may prefer, for instance, veratrum viride to either aconite or gelsemium, while another may prefer to use aconite in preference to any of the other cardiac sedatives I wish the *principle* to be ever present to your minds, and then you have your choice of several varieties of prescriptions

ATHEROMA OF THE LEFT CORONARY ARTERY RESULTING IN ANEURISM OF THE APEX OF THE LEFT VENTRICLE

Read before the Chicago Medical Society, June 6, 1887,

BY ROBERT TILLEY, M D,
OF CHICAGO

As this subject is so little associated with my usual practice it is with some hesitancy that I present even this short report Aneurisms of the heart, however, are not common in clinical reports, and I trust that fact alone will justify the presentation of the case

The patient was an intimate friend of mine, and it was only at his special request that I took charge of the case He was 57 years of age, and his occupation was that of a lawyer His previous life was unexceptionally exemplary He did not use tobacco in any form, and was exceedingly temperate and methodical in all his habits, his carriage was such as

to suggest the impossibility of any hurry on his part His general build may be characterized as corpulent, although when young he was very thin At the age of 30 he was declared to be dying of consumption Recovery, however, seems to have occurred without medical assistance

An ill defined malaise extending over a period of six weeks or two months suddenly increased to such an extent on the 20th of October, 1885, that he was unable to leave the house and was obliged to call assistance This malaise consisted of wandering pains, not severe, over the chest extending to the left shoulder and down the left arm, sometimes reaching the wrist They were not periodic, and could not be associated with any definite act of daily life, but would rather come on when any change of action was about to take place

He first called my attention to this, thus "I don't know whether I want to follow a doctor's directions or not I get occasionally flying pains over my chest and in my left shoulder, but on walking about a little I can make them disappear" As he always had a marked antipathy for medicine of any kind, and I did not possess any firm conviction of any greater benefit likely to follow anything I could suggest than the benefit he claimed from exercise, I told him to continue to use the method he had found successful, and report later At this time I had no conception of the existence in his case of atheromatous coronary arteries, nor did I suspect that the wandering pains were associated with incipient angina pectoris

About six weeks after the interview above referred to, an acute attack of difficulty of breathing, associated with severe coughing and anxiety of countenance, came on From this time he did not leave the house only for short walks The pulse at this time was 120, feeble but regular Breathing very laborious Could not lie down on the back or left side, and only for a short time on the right side Cough was very troublesome No special features present in the alimentary canal On percussion no perceptible enlargement of the heart was detected, percussion also failed to reveal any enlargement of the liver On auscultation the heart revealed no definite abnormal sounds The principal feature which I observed was that of a systole, the ventricles seemed to stop as though shutting down on a pledget of wool I find that Constantin Paul refers to this symptom very definitely as associated with aneurism, or what he calls false aneurism, of the heart It certainly struck me as the one striking feature of the case There was at this time no œdema, no fever, no albumin in the urine

From the beginning his condition was considered grave, and consultation was obtained from the first Drs H A Johnson and R H Babcock both saw the case, and the former remained as consulting physician to the end The various heart tonics, such as strychnia, arsenic, and digitalis, were used with no demonstrable effect except this, that when the digitalis was increased so as to diminish the frequency of the heart's action, the action became so tumultuous and incoordinate that it was deemed best to let it beat at the gait that it found most convenient In about a fortnight after the commencement of the acute attack anginal pains became more prominent, and atheroma of the coronary arteries was suspected There was no evidence, however, of any atheroma of any superficial vessels From this date a bottle containing carbonate of ammonia and camphor became his companion, supplemented with small pellets of nitro glycerine, 1-100 of a grain The latter gave more satisfaction than the nitrite of amyl The anginal pains were not at any time characteristic for their severity, but the pallor of countenance and anxious expression were characteristic Later on the feature of asystole was not so well marked The feet had exhibited, on several occasions, a tendency to œdema, but about ten days before death it began to increase rapidly, and no remedies were found capable of removing it The œdema extended gradually to the hips, abdomen, and chest, and about nine weeks after the acute attacks, while walking across the room, he fell dead

I would like to remark here that he derived marked comfort from gentle exercise with fresh air When the sidewalks were covered with ice so that he could not possibly walk out of doors, he would wrap up and walk in a room with the windows wide open Nitro glycerine and carbonate of ammonia were the only remedies that gave him any appreciable relief

The autopsy, which he himself requested—he had a horror of being buried alive—reveals nothing remarkably peculiar except the condition of the heart This autopsy was performed on the day following the death, by Dr Frank Cary in the presence of Drs H A and Frank S Johnson, R H Babcock and myself The heart was somewhat enlarged, all the valves were competent, there was little or no atheroma manifest except in the coronary arteries One of these I show you almost completely occluded It was just below this manifest atheroma of the left coronary that in the wall of the left ventricle near the apex the aneurism had developed I should characterize it as about the size of a large walnut The wall of the heart in the thinnest part was estimated by Dr F S Johnson as only two millimètres thick The aneurismal cavity was filled with blood, part of which showed signs of organization and part signs of disintegration The clot was evidently formed at two different periods The microscopic sections for which I am indebted to the kindness of Dr F S Johnson shows this well There were no signs of chronic endocarditis, but some of slight chronic myocarditis

Bramwell divides aneurisms of the heart into acute and chronic Constantin Paul calls such cases false aneurisms, and then adopts the same division "Acute Aneurism," says Bramwell,[1] "may result from anything which causes rapid local softening of a limited portion of the cardiac wall Acute ulcerative endocarditis, acute localized myocarditis and acute softening the result of thrombosis of the coronory arteries are the conditions which are most likely to cause acute local dilatation of this description"

[1] Bramwell Diseases of the Heart p 576

"Chronic aneurisms of the heart," he continues, "are almost always the result of chronic myocarditis Fatty degeneration seems to be an occasional though extremely rare cause of this condition" He nowhere calls direct attention to an atheromatous condition of the coronary arteries as a cause Constantin Paul speaks of a case under his observation where there was an atheromatous condition of the aorta and he supposed this to be the starting point in the case that he reports

Dr Mary Putnam Jacobi says (in Wood's Reference Handbook) "The essential cause of heart aneurism is thus identical with arterial aneurism, the lesion of structure is however different as might be expected from the difference of tissue in the heart and arteries In the latter, that is, the arteries, non-traumatic aneurism nearly always depends on atheroma, in the former upon fibroid disease the result of chronic interstitial myocarditis"

In the present case, I think, there is no doubt that the starting point was the diminished calibre of the left coronary artery by this atheromatous condition diminishing the supply of nutriment to the corresponding tissue and thus producing the extreme thinness of the walls in the part supplied by the artery The clot of blood was probably the result of the incapacity of the left ventricle to completely contract and expel its contents and probably occurred in part at the time of his acute sickness about 9 weeks before death

The presence of this clot of blood fully explained the characteristic sound which I clearly recognized at the first and which I described as though the ventricle contracted on a pledget of wool

---

COCKLE-BUR REMOVED BY TRACHEOTOMY FROM THE LARYNX

Read before the Medical Society of the District of Columbia, May 4, 1887

BY J FORD THOMPSON, M D,

OF WASHINGTON, D C

W D, white, æt 16, admitted to Children's Hospital, 8 30 P M, April 20, 1887 He was brought to the Hospital by Dr Stone, of Brightwood He was playing ball, having a cockle-bur in his mouth, which he drew into his larynx by a deep inspiration following violent exertion Violent coughing ensued, accompanied by bloody expectoration, total aphonia, and considerable dyspnœa Dr Stone saw him immedtately after the accident, but was unable to remove the bur with the instruments at hand Concluding that tracheotomy was called for he brought the boy to the hospital, having telephoned me to be on hand to operate

When I saw him he was breathing so quietly and easily that I doubted the presence of any foreign substance in the wind pipe, although there was tenderness about the larynx and he would not make an effort to talk I passed an œsopheal bougie down to the stomach without result I then passed my index finger into the larynx and readily detected the bur Free emesis followed, but no relief Considering it a case for extracting by the aid of the laryngoscope, and not having the necessary instruments in the hospital at the time, I determined to take him to Dr C E Hagner's office Dr Hagner and Dr Murray, who happened to be present, examined him and readily saw the bur Dr H made repeated efforts to extract it but failed He was sent back to the hospital with instructions to watch him closely during the night and to administer bromide of potassium, and apply wet cloths to the neck

April 21 10 30 A M Had passed a fairly comfortable night, refused to take any nourishment Present Drs Hagner, Triplett, Stone, Cutter, Mundel and the house assistants Dr Hagner used the mirror but did not see the body, considerable mucus in larynx He was still breathing easily, with no cough I decided to open the trachea at once After chloroform was administered, I cut through the two upper rings of the trachea, and as this opening was not sufficient, I extended it through the body of the cricord I inserted a loop of silk to each side of the cartilage to keep the wound open, as they were less in the way than the retractors I made every effort to detect and grasp the body with tracheal forceps but failed I then introduced the index finger of my left hand into the larynx and readily felt the bur, which was to the left side, probably in the ventricle I introduced the curved forceps through the wound and dislodged the body, and with the aid of the fingers in the larynx pushed it upwards and extracted it through the mouth I inserted a tube which was left in for 24 hours

April 22 —Rested well during night Temp 99° Tube taken out

April 23 —Doing well Lower part of wound healed by first intention, the tube opening left to heal by granulation

April 24 —Speaks in his natural tone, appetite good

April 30 —Discharged cured

I would call especial attention to the ease and thoroughness of exploration of the larynx by the fingers as shown in this case I scarcely believed it possible before to do it so readily and so satisfactorily

Other cases reported are

1 Cockle-bur in larynx Drs Brown and Van Note S C, æt 11, running across a field, fell, cockle-bur flew in mouth and into larynx Respiration labored and voice of a croupy whisper Introduced probang into stomach to be sure it was not in œsophagus Could not remove with forceps so 48 hours after accident performed laryngotomy Bur in right ventricle Recovery

2 Cockle bur in larynx S T Armstrong, M D, Asst Surg U S Marine Hospt Service, Memphis, Tenn S Miller, colored, æt 11, while running in a field with mouth open inhaled cockle bur which was blown by wind Oct 14 Breathing difficult, deglutition painful Palliative means used by a physician of Memphis Dr A saw him in consultation at 16 Curved forceps used but failed They were then introduced through incision but failed to dislodge or grasp it Finger introduced in mouth

and with aid of forceps through incisions brought out through mouth

3 Cockle bur in larynx Geo W Norman, Sweet Mills, Ky, Oct 24, 1879 Bur lodged in larynx by inhalation during some exertion Free vomiting and coughing failed to dislodge it Tracheotomy was performed next morning and wound left open 6 days At the end of that time it was coughed up Recovery

MEDICAL PROGRESS.

ARTIFICIAL AND COMBINED DRAINAGE OF THE BLADDER, KIDNEYS, AND UTERUS THROUGH THE VAGINA, WITH AND WITHOUT GRADUATED PRESSURE —DR NATHAN BOZEMAN, of New York, read a paper on this subject in the Section on Gynecology of the IXth International Medical Congress He described an instrument which he had devised recently This draws the uterine away from the mucous membrane, and in the most perfect manner He has also been able to combine in the same instrument drainage with the dilatation of the cicatricial tissue of the vagina The form of the instruments which concerns us here is intended for drainage alone, and I have called them intra vaginal and vulvo vaginal drainage supports The intra-vaginal instrument is applicable in most cases to all positions of the body The vulvo vaginal form is suited to the recumbent position, and to cases where the perineum is lacerated These can be introduced and removed by the patient when necessary They are small and simple, free from angles and sharp bodies, are readily kept clean, and excite no discomfort or irritation of the vagina They do not press on the rectum or vagina, nor do they interfere with locomotion

The author closed his paper with the following conclusions

1 The importance of completion of the operation for fistula has not been duly appreciated This forms, in many cases, the principal difficulty in the successful performance of the operation for the closure of the fistular opening In other cases, when the fistula is cured, but the complications left without treatment, they lead sooner or later to the death or suffering of the patient The greatest care should therefore be taken to discover and remove them

2 Kolpokleisis, occlusion of the os uteri, and incision of the cervix in the bladder or rectum, are unjustifiable operations They destroy the functions of the generative organs, lead to cystitis, then form venereal and vesicular calculi, pyelitis, and other diseases Moreover, they are unnecessary By means of the preparatory treatment of the complication by the aid of my button suture and my dilating speculum, I have been able to overcome all the difficulties which have been described as indications for operation

3 The association of combined drainage in the dilatation of the vagina is a great improvement The inconvenience and evil effects of incontinence of urine are thereby lessened, and the duration of the treatment shortened by the more rapid healing of the incisions and the formation of less cicatricial material in the reparative process

4 We now propose a means of palliating the suffering due to incontinence of urine in a small proportion of cases of fistula which are incurable by this method—even the dangerous one of kolpokleisis I believe that some form of drainage may be instituted in every case, and the patient may be thus restored to enjoy life and the performance of its duties

5 The possession of a system of combined drainage will widen the scope of the operation of kolpocystotomy, done for cystitis, by removing the evils of incontinence of urine, now the chief objection to its performance

6 Finally, I think the operation which I call kolpourethro cystotomy, followed by the exploration and treatment of the disease of the uterus and pelvis of the kidney, has a brilliant future before it In the treatment of pyelitis, renal calculi, and obstruction of the ureters, it will restrict within narrow limits the operation of nephrotomy and nephrectomy

DR GRAILEY HEWETT, of London, said The paper just read had shown decided advance in this line of thought Conservative surgery, in this our day, seems to be running a race with operative surgery He endorsed the views of the essayist thoroughly—*Medical Record*, Sept 10, 1887

GALVANISM IN PRURITUS VULVÆ —DR H VON CAMPE, of Hanover, reports the results of a mode of treatment to which his attention was directed by a communication from W Blackwood, which first appeared in the *Polyclinic*, 1885 Von Campe was consulted in the beginning of August, 1885, by a woman aged 53, who was suffering from an intense itching of the vulva, groin, perineum and anus The patient had always been healthy until 2½ years after an abortion, when she had irregular discharges of blood from the uterus, to remedy which the organ was curetted After the curetting the discharges of blood never recurred, but she suffered from a profuse acrid discharge In spite of various modes of treatment the condition was not remedied, but itching began in the vagina and extended gradually over the mons veneris, groin, perineum and anus The patient consulted various physicians, one of whom even excised portions of the integument where the irritation was most intolerable, but no measure of treatment resulted in more than slight temporary relief She had long employed injections and solutions of carbolic acid and sugar of lead, but with only slight effect

After trying salicylic ointments and cocaine, which alleviated the distress for only a few hours, von Campe resorted to galvanism on September 21, using at first a current from 6 elements with the anode applied to the vulva and the cathode to the affected portions of the integument The sittings lasted 10 minutes A weak solution of carbolic acid was also prescribed, to be employed night and morning Two days later the patient reported that the pruritus left

her immediately after the application of the current and that she had enjoyed a respite of several hours The patient was then subjected to the galvanic treatment on the three following days, during which time her condition improved Six more applications were made before October 8, with a current from 8 elements, and at this time the pruritus had nearly disappeared, leaving only a slight prickling pain The integument had healed over in spots and the skin looked quite natural The patient reported that she was able to sleep all night for the first time in five years Two more applications of galvanism were made before October 16, by which time the pain had quite disappeared and the skin had nearly healed Treatment was reapplied on October 24, 25 and 26, from which time until November 20 she was entirely free from the pruritus Then experiencing a slight return of the trouble, she returned and the parts were again galvanized several times, after which the affection of the skin entirely disappeared Since then the patient has often been heard from Pruritus is occasionally felt, but only in a slight degree For the most part the discharge has continued, but it is much less profuse Both conditions are easily controlled by the use of weak douches of carbolic acid —*Centralbl fur Gynakol*, No 33, 1887

ACTION OF QUININE AND ALLIED SUBSTANCES ON CONTRACTILE TISSUES —In a paper on this subject read at the late annual meeting of the British Medical Association MR R B WILD draws the following conclusions from a series of experiments

To summarize the results of my experiments, I believe that quinine acts essentially in the same manner on all forms of contractile tissue In small doses it stimulates, as shown in the heart, the increased height of contraction of voluntary muscle, and the initial contraction of the vessels

In larger doses, or after longer action of small doses, it completely paralyses the contractile power of the tissue, this is seen in the arrest of amœboid movement, the cessation of response to stimuli in voluntary muscle, the stopping of the heart in diastole, and the dilatation of the vessels

In very large doses, or after very prolonged action, quinine causes contractile tissues to pass into a state of rigor mortis, as shown by the small spherical condition of leucocytes, the rigidity of voluntary muscle, the contracted state of the heart, the secondary contraction of the vessels after long exposure to the poison, and the contracted state of the œsophagus

Voluntary muscle (that is, the tissue in which contractility is developed to its greatest extent) was most susceptible to the action of quinine, and was thrown into rigor mortis by solutions which produce paralysis only of the less specialized tissues, with strong solutions (for example, 1 000) voluntary muscle passes into rigor mortis so rapidly that the period of paralysis is abolished, and the tissue, after a short period of increased contraction, passes directly into a rigid and contracted condition

I have not the time to enter into the action of other drugs allied to quinine, shortly, I found cinchonine to act like weaker solutions of quinine, cinchonidine had a similar but more powerful action on voluntary muscle than quinine, quinidine, on the other hand, acted as a direct depressant, the muscle dying with great rapidity —*British Medical Journal*, Sept 3, 1887

COLD WATER IN TYPHOID FEVER —DR S P ALLEN, of Whitney's Point, New York, says The following conclusions, which were given by Dr Austin Flint, after closely watching the effects of cold water externally in the treatment of 17 cases of typhoid fever that came under his care in Bellevue Hospital some years ago, are sustained by the results in 13 cases that occurred in my practice since that time

1 That by the use of cold water externally in cases of typhoid fever the temperature of the body may, after a variable time of its continuance, be reduced to 102°, or even lower

2 After a period varying very much in different cases, and also at different times in the same case, the temperature rises as high or higher than before the reduction

3 Upon repeating the employment of cold as often as the axillary temperature exceeds 103°, the number of repetitions necessary is extremely variable in different cases

4 The sponge-bath, with the wet sheet and sprinkling, may be employed to the exclusion of the bath tub in the treatment of typhoid fever

5 These modes of employing cold water may be continued sufficiently long for the reduction of the temperature to 102°, or even lower, and repeated as often as may be required, without fear of injury And the study of these cases furnishes no ground for supposing that a liability to complications or accidents is thereby increased, and that the reduction of the temperature by these modes, as often as it rises above 103°, improves the condition of the patient

6 The results of the analysis of those cases where cold has been faithfully used, afford us encouragement to employ it with the expectation of diminishing the severity of the disease and its danger to life —*Medical Times*, Sept 3, 1887

SPARTEINE, A HEART STIMULANT —LANGGAARD reports the following formulæ, which he found useful in 18 cases of heart diseases

℞ Sparteïn sulph gr 6
Pulv rad liquirit
Succ liquirit ää q s
Ft pil 20 in num
Sig One or two pills from 2 to 4 times daily

Also

℞ Sparteïn sulph gr 3 to gr 7
Ad destill ʒ 2½
Solve
Sig Twenty drops, from 2 to 4 times daily, in sweetened water or wine

℞ Sparteïn sulph gr 3 to gr 7
Syr aurant cort ʒ 12½
Solve
Sig A small teaspoonful in water, from 2 to 4 times daily
—*Therapeutische Monatschefte*, June, 1887

THE PHYSIOLOGY OF DERMATO THERAPEUTICS

Dermatology is a subject to which the general practitioner probably pays less attention than he does to any other department of medicine, except, perhaps etiology—a fact which is most probably due to the little attention given to the subject in the college courses Yet our readers may be interested in an analysis of a paper read at the late annual meeting of the British Medical Association by one of the great masters of dermatology, DR P G UNNA, of Hamburg For many years there has been a vast amount of discussion as to the absorptive power of the skin, and it is not very long since physiologists carried the day against the balneologists and general practitioners, and proved that the absorptive power of the skin is very limited But while it has been shown that indifferent salts, applied to the outer skin in the form of ointments, pass into the circulation in very minute quantities, we have at the same time learned that volatile substances, and such as attack the horny layer of the skin, even to the slightest extent, are absorbed by the skin without difficulty With this fact before us we must arrange our medication on this principle when we wish to pass through a thickened or normal horny layer in order to reach a deep seated focus of disease

Of course what has been said of the limited absorptive capacity of the skin does not hold good when there is no horny layer to deal with, as in cases of ulcers in which the papillary layer is necrosed, or in pustular processes, burns and wounds, or in cases in which the upper strata of the horny layer are absent, though the basal cells are still present, but swollen, as in eczema, pemphigus and other bullous affections It should be borne in mind, however, that the horny layer itself is not what prevents the absorption of certain substances through the skin, but its property of attracting and absorbing the skin fat, which renders it impermeable But in the majority of skin diseases we have to take in account an absorptive power of the skin or what is left of it, that is greater than the normal While the natural horny layer opposes the entrance of medicinal substances, the diseased portions of the skin take them up readily, and the drugs act more promptly and powerfully on these than on the healthy portions of the skin Again, the diseased skin " controls up to a certain point the selective action of the drugs and regulates their effects, so that it is the morbid portions which are chiefly affected " This selection of diseased organs for remedies which are intended to act on them is not an infrequent occurrence But it is not enough to bring the needed drug in contact with the surface In some cases the horny layer is normal or hypertrophied, and yet an intense penetration is very necessary, in order to remove deeply situated germs of a fungoid nature, and of an infectious kind, such as lupus, lepra, lichen ruber, psoriasis, furunculosis Again, there are many dermatoses in which at least a part of the horny layer is laid bare, but in which the absorption—the centripetal suction—of the drugs is opposed by the strong centrifugal floor of the tissue-juices permeating the swollen scarf skin Such cases are weeping eczemas, impetigenous eruptions, ulcers (as of lupus), and all profusely secreting surfaces The mode of application of the medicine in these cases is of great importance, and in many cases treatment gives only failure, because of the insufficient consideration of the peculiarities of the skin in the particular cases, as regards the form and manner of applying the remedies

The agents used as applications to the diseased skin may be classified as chemical and mechanical, the former being used to modify the skin in the way desired The most important keratolytic agent known is salicylic acid, being far more certain and controllable than soap or caustic potash, though in some cases it is not applicable while the others are To harden the swollen and defective horny layer, on the other hand, and make it thicker and drier, so that it may be able to take up more fat, we use such keratoplastic agents as sulphur, ichthyol, resorcin, sugar, linseed oil, and all the reducing agents In these cases there is a reduction or withdrawal of oxygen, and the keratoplastic action is limited to cases in which these agents are used in dilutions of definite weakness, and if this limit be exceeded the keratoplastic action

ceases, and a keratolytic action begins These keratolytic and keratoplastic substances are now extensively used, either as independent remedies or as adjuvants or correctives to other drugs, and when the physician makes a proper choice and combination of them his labor is much lightened

The mechanico physical therapeutics of skin diseases consists in using the volatile and gaseous substances that pass readily through the horny layer of the skin To these may be added substances, themselves but little volatile, which are readily soluble in such volatile vehicles as ether, chloroform and benzine, hence the proposal of the spraying on the diseased skin of drugs dissolved in these vehicles, a method to which but too little attention has been paid Not only can the horny layer, impregnated by fat, be penetrated by means of the volatile spray, which dissolves out the fat, but when this is used on a deficient and swollen horny layer it has a drying effect by causing the abstraction of water Unna has often cured eczemas by means of the pure alcohol spray, and superficial *fungoid affections with the chloroform spray* "The oleates, the powers of which when used in salves are often over-estimated, attain their highest utility when employed in solution in the ether spray"

There are certain physical means also, to understand the application of which one has to remember the anatomy and physiology of the skin The principle underlying these methods is that the products and secretions of the skin, which are notably partly of a fluid and partly of a fatty nature, are either accumulated or got rid of by artificial means Practically we need consider only three products of the skin 1 The water-vapor or insensible perspiration, which is continually evaporating over the surface of the body 2 The watery sweat 3 The fatty sweat The first makes up about 77 per cent of the whole water evaporation of the skin, and can only be suppressed by a warm or a steam bath, its suppression being compensated for by a large increase of the watery sweat By means of a partial stoppage of this we can soften the horny layer But it is much easier to cause retention of the fluid sweat, both watery and fatty, for example, by a permanent water-bath, which causes an accumulation of fat in the upper skin, and this keeps back the watery secretion, and much better in normal conditions than inunction with fats But in many skin-diseases watery secretion is enormously increased by over-filling of the papillary vessels, and in such cases inunction is of service the redness and inflammation of the eczema or rosacea may be increased by the fatty substance, but this maceration and higher temperature may be just what is desired, and the fat should be put on in a thick layer But by the use of gutta percha or india rubber the secretion may be still more completely retained In this way the upper skin is completely soaked with water, and the horny layer becomes like the epithelial lining of the mouth At the same time it contains but little fat, and is very permeable, and non-resistant to watery solutions It is a mucous-like substance When we wish to obtain the greatest possible effect of a drug upon the skin, therefore, it must be applied under an impermeable covering

---

Under certain circumstances, again, it may be desired to extract and eliminate the masses of fatty and watery secretion when they are formed in abnormally large quantities, as is the case in some skin diseases Here we apply dry porous substances to the skin, so as to cause rapid absorption of the water and fats, such as rice-powder, and the pastes and gelatines now extensively used As the most vigorous absorption through the skin takes place under impermeable coverings, so with these powders, pastes and gelatines, when incorporated with drugs, absorption through the skin is reduced to the lowest limits They strengthen the centrifugal stream of secretion, and thus bring the centripetal, or stream of absorption, to the lowest limit They dry up the horny layer, and thus increase the difficulty with which fluid substances pass through it If, therefore, we apply volatile substances in the form of pastes and gelatines we can only look for deeply penetrating effects, and as they volatilize more easily towards the air than through the skin, it is injudicious to apply them in this manner Under the impermeable coverings, therefore, the watery elements at once get the upper hand, while under porous bodies the fatty elements are stored, while the watery pass through and are quickly evaporated Both these kinds of preparations act, therefore, on the stream of secretion, the one restricts secretion and favors absorption through the skin, the other promotes secretion and reduces the power of absorption through the skin The different methods are mutually complementary, and cannot replace each other "Only he who has them to a certain degree at his command can say that he knows and can make use of the modern method of dermato therapeutics"

EXTIRPATION OF THE UTERUS IN CARCINOMA

PROFESSOR HEINRICH FRITSCH has recently contributed (*Centralblatt fur Gynakologie*, No 25, 1887), the tabulated results of 60 operations for total extirpation of the carcinomatous uterus From

his paper it appears that 10 per cent of the patients died from the effects of the operation, a mortality which corresponds to that of laparotomy in general Of the survivors 20 thus far remain without recurrence, in 2 cases a period of more than 3 years has elapsed since the operation, in 7 cases more than 2 years have elapsed, while most of the other patients have already passed the most dangerous period—the first 6 months From this Fritsch makes the point that after total extirpation of the carcinomatous uterus recurrence occurs less frequently than after operations for carcinoma in other localities, the reason for this being, probably, that the advance of the carcinomatous process in the lymphatics and the formation of metastases takes place much less readily in the case of the non active uterus than in the case of such an active organ as the breast, which makes strong demands on the lymphatics This view is confirmed by the comparative infrequency with which the disease returns in multiparous and old women

As regards the operation, a necessary condition is movability of the uterus Parametric fixation prevents the drawing down of the uterus, but pelvic fixation does not The size of the carcinoma is of less consequence Especially unfavorable are those cases in which the uterus itself is destroyed, and the parametrium infiltrated, while the portio vaginalis remains healthy, since in such cases a recurrence of the disease is unavoidable, and it is better to abandon the operation, according to Fritsch Even the hope, which he formerly entertained, that pain would be removed even though the disease returned, has not been realized, for cancerous nodules develop in the rectum, giving rise to excessive pain The field of operation, he says, is most readily made apparent by cutting into the parametrium, and if nodules of cancer be found here the operation must be abandoned Fritsch's method offers great advantage in that it begins with lateral incisions, the peritoneum not being opened until later in the operation, so that if the parametrium be found diseased the operator may stop, tampon the wounds with iodoform gauze, and leave the patient in no worse condition than before If it be found difficult to draw down and remove the ovaries Fritsch leaves them *in situ*, even in the case of women who still menstruate But usually after the removal of the uterus a slow steady pull on the ligatures suffices to bring the ovaries down

The opening in the peritoneum is not sutured, but is merely closed by an iodoform tampon, and in using this method Fritsch has never had any trouble from prolapse of the intestines It is not necessary after the operation that the patient maintain any especial position in order to facilitate the escape of the discharges, but she has simply to lie on her back

A moderate increase in the size of the uterus does not materially increase the difficulties of the operation, provided the operator remember to draw down first on one angle of the uterus and then on the other But the presence of myomata may render the removal of the organ *per vaginam* impossible In such cases a laparotomy must, of course, be performed, and does not greatly increase the danger of the operation In some cases Fritsch has found a vagina so distensible that he was able to draw through it a uterus as large as a child's head In such cases the danger of wounding the bladder is of course increased, and should this accident occur the wound must be closed immediately But if a wound be not discovered until after the operation it is better to leave it until the patient has recovered from the first operation The ureters are seldom injured during the removal of the uterus

In regard to prognosis, a rapidly recurring carcinoma will always appear in the cicatrix, while if it does not recur until later it will be found to affect the ligaments by preference A smooth transverse cicatrix in the vagina gives a better prognosis than a hard irregular one In order to improve the prognosis of this operation, which has already been shown to be justifiable, the cooperation of general practitioners is necessary, so as to bring the case to operation as soon as possible

CREASOTE IN PHTHISIS

According to the *Medicinische Chirurgische Rundschau*, No 6, 1887, Dr Sommerbrodt, of Breslau, has reported 5,000 cases of pulmonary tuberculosis treated with creasote, all being ambulatory cases, the series extending over nine years A number of patients were treated with Bouchard and Gimbert's formulæ, 27 per cent recovering Other formulæ used were 13 5 parts (?) of creasote to 1 quart of alcohol or Malaga wine, 2 parts of creasote to 150 of cod liver oil The dose of these preparations was the same, from 3 to 5 ♏ of creasote being taken daily Another formula used was creasote 3 5 parts, alcohol and water of each 125 parts, one teaspoonfull twice daily in a glass of water This was used in 30 cases The best results were obtained from the following Gelatin capsules, each containing ♏ ¾ of creasote and ♏ 3 of balsam of tolu On the first day of treatment the patient took one of these

capsules, two on the second day, and for eight days afterwards three were taken with water after meals In the second week four capsules were taken daily, in the third week five capsules daily, and in the fourth week six daily, after the principal meals of the day Given in this way the drug was well borne as a rule This medication was frequently continued for a year, and sometimes combined with favorable climatic treatment It was in young patients that the best results were obtained, and in the first stages of the disease, with symptoms not well defined Good results were also obtained in scrofulous affections of glands

The drug seemed to relieve irritation and cough, in many cases to such an extent that narcotics could be dispensed with Bronchial secretion and night sweats were also diminished Sommerbrodt says that the drug must be taken for three months or a year, and that the more of it taken the better the results With such an array of cases as he presents, and with the results he has obtained, it certainly seems that the method is well worthy of trial

---

CHOLERA —It is well known that this disease has recently been on the increase in some parts of Italy and the Island of Sicily The first importation of well-marked cases in our country was made by the steamship "Alesia," from Naples, Italy, which arrived at the New York quarantine on the night of the 22d September, 1887, with four cases of cholera on board Eight deaths from the same disease had occurred during the voyage Prompt measures were taken to retain the passengers in quarantine, the sick in hospital, and to have the ship thoroughly disinfected and cleansed It is not probable that, at this season of the year, the disease will extend beyond those belonging to the ship

---

A SANITARY CONVENTION, under the auspices of the Michigan State Board of Health, will be held at Owosso, Michigan, November 22 and 23, 1887 The first session will commence at 2 P M , of the 22d, and will be free At each session papers on subjects pertaining to the public health will be read and discussed, in such manner as to interest and profit all classes of citizens For further information address Dr A M Hume, Secretary, Owosso, Mich

---

YELLOW FEVER —The prevalence of this disease at Key West, Fla , appears to have run its course and ceased without extending to other places No new cases were reported for the week ending September 22, and only one death

SOCIETY PROCEEDINGS.

CHICAGO MEDICAL SOCIETY

Stated Meeting, June 6, 1887

THE PRESIDENT, WM T BELFIELD, M D , IN THE CHAIR

DR FRANK BILLINGS exhibited a very interesting collection of

BACTERIAL CULTURES

and explained the mode of their culture, and gave the name and description of each bacterium

THE PRESIDENT asked whether this method of culture was not of extreme value in differentiating the different sorts of bacteria one from another, and whether this did not enable investigators to distinguish the different sorts of bacteria

DR F BILLINGS At the present time there are three comma bacilli that are well-known the comma bacillus of Asiatic cholera, discovered by Koch, the one discovered by Deneke in old cheese, and the one discovered by Finckler and Prior These under the microscope look so much alike, that one would not dare to differentiate between them, but their growth in gelatine tubes is so characteristic that one can easily tell the difference The cholera bacillus grows upon the plate in a peculiar granular colony, that does not make the gelatine fluid so quickly as the bacillus of Finckler or Deneke Finckler makes the gelatine in tubes, fluid from above downward, first where the needle is run into it and again at the top Those found in old cheese make it fluid in the same way, but less quickly, while the cholera bacilli grow in a characteristic funnel-shaped form Then of the staphylococci, there is the styphylococcus pyogenes aureus, the staphylococcus pyogenes citrius, and the staphylococcus pyogenes albus, these are called white, orange and lemon color by their characteristic growth on culture media, *in time* one will be white, one orange and one lemon color, but in the first week one could not tell the difference It is quite as important to know how to cultivate bacteria and detect the difference in growth as to know how to differentiate bacteria with the microscope by their form and their reaction to the aniline dyes

DR LESTER CURTIS read a paper on

CALCARIOUS CONCRETIONS IN THE EXTERNAL EAR

The following case, occurring in an old patient of mine, has seemed to me to be unusual I had treated the patient for several years for slight ailments, chief of which was an occasional malarial attack that gave me some trouble on account of her inability to take quinine

In August, 1886, she called my attention to a painful swelling in the external meatus of the right ear I considered it to be a case of ordinary superficial inflammation of the meatus and directed instillation of a solution of morphine The pain at once ceased, and in a day or two the swelling sub

sided, and I supposed that the trouble had resolved, as has usually occurred in my experience after such treatment But a little swelling and tenderness remained In about two weeks, without further symptoms than a trifling uneasiness, there was a discharge of a drop of purulent fluid which I am sorry that I had no opportunity of examining I paid no more attention to the case until about a month after this, when she called at my office, and told me that the same morning the ear had felt a little uncomfortable, and on picking it, a calcarious mass about as large as a millet seed had come away A day or two before she had removed a similar mass These masses, she said, resembled lumps of old lime as nearly as anything she could think of On examining the ear I saw a red and indurated place about half way down the meatus, in the upper portion of the posterior wall In the middle of this spot was a pit about as large as the mass removed, and surrounding the pit a greater or less amount of a white granular substance which grated against the probe and was of stony hardness I attempted to detach some of it with the sharpened end of the probe, but it was firmly adherent, and appeared to be infiltrated throughout the tissue, and I succeeded in getting away only a few small flakes Besides this nothing unusual was detected in the ear with the exception of a slight redness of the posterior rim of the drum head The hearing was perfect A slight feeling of irritation was noticed for some weeks, but gradually passed away At present, so far as I can discover, the ear is quite normal

I do not think that there is any possibility of the concretion being a foreign body, nothing with the exception of the morphine was introduced into the ear, and that could hardly have produced such an effect, besides, part at least of the substance was infiltrated among the tissues of the meatus Superficial abscesses in which there is a free discharge of pus do not undergo calcareous degeneration The appearance was that of a gouty concretion, and there is a trace of gout in the family Her father, though an active and abstemious man, having had slight attacks of the affection, but she has never had any gouty symptom that I have been able to discover, and gout does not suppurate I have never heard of a case like this, and the somewhat limited amount of literature on diseases of the ear, accessible to me, makes no mention of anything of the kind

Dr R Tilley thought the author should have examined the concretion microscopically and determined its nature For himself he was of the opinion it was probably composed of dried epithelia resulting from a partially absorbed furuncle

Dr Lester Curtis I have no special reply to make to the conjectures I never examined the ear of the patient before this thing occurred but I have examined both ears since that time and so far as I could see there was nothing in the shape of a sebaceous cyst in either ear One would naturally suppose that if such things occurred there would be more than one of them I would imagine if one should occur in such a locality there would be likely to be others One word in regard to treatment I used, which I have recommended in a considerable number of cases and always with benefit While I have never used the rubber tube, I have seen a good many cases where I would not venture to insert it The solution of morphine will quiet pain in every case And in every case I have happened to meet, it has stopped the inflammation and the pain has not recurred

Dr W L Axford I would suggest that the case was one originally of sebaceous cyst, that the contents of the cyst had undergone calcareous changes and afterwards inflamed I have seen that happen in the head but never in the ear

Dr W L Axford read a paper for Dr O G Miller on

A GUIDE FOR THE OTIS' URETHROTOME,

in which the mechanism and workings of the guide were fully described

Dr R Tilley reported a case of

ATHEROMA OF THE LEFT CORONARY ARTERY, RESULTING IN ANEURISM OF THE LEFT VENTRICLE

(See page 430)

Dr Robert H Babcock It was my good fortune to see the patient to whom Dr Tilley has referred this evening, and as it was a case of remarkable interest and there are several points illustrative of the peculiar symptoms due to atheroma of the coronary arteries and also illustrative of the difficulty, many times of diagnosticating the condition, I would like to refer to them The first symptom mentioned by Dr Tilley as important was that of angina pectoris, and herein this case was peculiar, the pains were flitting and were relieved by gentle exercise It was wholly characteristic, however, in that the pain extended to the left shoulder and down the left arm That is the characteristic pain of angina pectoris, although there are so many deviations from it that angina pectoris frequently passes unrecognized by the general practitioner There is a liability oftentimes to mistake angina pectoris for neuralgia of the stomach I have under observation a case where the pain has been considered for years gastralgia, but it is without doubt angina pectoris, the arteries are atheromatous and there are characteristic cardiac murmurs which are due to the atherosed condition of the valves The pain of angina may sometimes be localized in the wrists Dr Sawyer once mentioned to me a case in which the angina pectoris always manifested itself by a feeling of cord like constriction about each wrist There was, however, with this an attendant paleness of the countenance and anxiety and the patient was obliged to stop in his tracks until the pain had passed The pain in angina pectoris may extend through to the back, or up into the occiput, at other times into the right shoulder and down the right arm It may also radiate into the abdomen and down the inside of the thighs It is usually so severe that the patient has to stand still and wait until the pain passes by In the case mentioned the pain was relieved by gentle exercise, and that possibly may throw some light upon the question as to whether angina pectoris is always due to arterial spasm or not If due to arterial spasm in all cases

it would seem as if any effort of the muscular system would increase the arterial resistance through contraction of the muscles and thus make a greater demand upon the heat, in which case exercise ought to augment rather than relieve angina pectoris Particularly if as Leyden is inclined to think angina pectoris is really due to spasm of the coronary arteries as well as general arterial spasm, resulting in temporary anæmia of the heart muscle In cases where the paleness of countenance would seem to confirm this theory we find that remedies which produce arterial dilatation, such as the nitrite compounds, always give relief In this case there is an apparent contradiction, not only did exercise afford relief which would seem to indicate that contraction of the peripheral vessels had nothing to do with the production of the angina, but on the other hand since nitro glycerine gave relief, there must have been arterial spasm somewhere

The diagnosis of this case was not as difficult as is often the case, owing to the peculiarity of the cardiac sounds, although none of us I think really suspected the condition which we found of the coagulum in the left ventricle filling up the lower third of the cavity I gave my diagnosis of degeneration of the left ventricle, with atheroma of coronary arteries, because of the very peculiar character of the sound over the left ventricle which Dr Tilley has very aptly described It was a toneless, muffled sound as if the heart struck the chest wall through an intervening layer of cotton, while on passing the stethoscope from the left ventricle toward the right ventricle the first sound came out with its usual clearness and more or less of its booming quality, and it was on that that I based my diagnosis At the post mortem examination we found degeneration of both ventricles, more marked in the left than in the right This case would probably be classified by Leyden as subacute Leyden has treated this subject in the most scientific manner of any author, since generally the subject is treated in a desultory way under the various heads of chronic myocarditis, fatty degeneration, aneurism, rupture of the heart, etc

Leyden would group together all the different expressions of the same pathological condition, that is sclerosis of coronary arteries and all conditions dependent upon that, and he considers it under one subject of the changes of the heart resulting from the sclerosis of the coronary arteries He recognizes as acute cases those in which the patient is ill perhaps for a few moments or hours or days The first symptom is often a sharp attack of angina pectoris, or an attack of great cardiac distress and oppression without positive pain, which Gairdner speaks of as *angina sine dolore* In these cases the patient frequently first discloses that he has heart disease by falling dead in his tracks In cases of atheroma of a small branch of the left coronary artery, usually the anterior descending branch, frequently we find a condition closely resembling the hæmmorrhagic infarctus and the heart ruptures at that point, in acute cases death may be due to the rupture, although more often to failure of the heart Subacute cases, of which this seems to be an example, run their course in a few weeks or months and we find a combination of changes from acute fatty softening to chronic fibroid change, and these patients generally suffer a good deal with angina pectoris The chronic cases are those that last for years, sometimes fifteen or twenty, and the symptoms are those of cardiac weakness or progressive cardiac failure, and these patients may die suddenly or gradually In these cases we generally find extensive myo carditic changes with great thinning of the heart walls

The treatment of these cases is of course a thing which interests us It is very unsatisfactory, is merely palliative, and consists chiefly, in the severe cases, of rest, with cardiac tonics and stimulants Of especial service in angina pectoris are the nitrite compounds, although Leyden rather protests against the use of nitrite of amyl and nitro glycerine He recommends the hypodermic injection of morphine, stimulants, such as ammonia and camphor, hot alcoholic drinks, and heat to extremities The diagnosis has to be based, in most of these cases, upon the history and symptoms of progressive or sudden cardiac failure, and if we can find evidence of atheromatous change in the peripheral vessels the diagnosis is much easier In auscultating these cases I have frequently found what seemed to me to be a peculiarity of the first sound The sounds of the heart are nearly always described as free from murmurs, but since the booming quality of the first sound is undoubtedly due to the muscular element, and since the muscle of the heart is degenerated, the first sound takes on rather a short and valvular quality resembling very closely a second sound, so that frequently in these cases the two sounds appear to be two valvular sounds Although I am not yet prepared to say that one can base a diagnosis upon such a condition as that, yet I am satisfied that in cases where there has been marked atheroma of the radial arteries, with symptoms of heart failure, I have heard just this condition of shortness and valvular quality of the first sound over the left ventricle, particularly when over the right ventricle the sound is more prolonged

Dr Tilley said I have nothing more to add except that I have known of two or three cases in which, after a hypodermic injection of morphine, in a condition of atheromatous coronary arteries, the patient has passed off very rapidly, and I would be chary of using it, especially if I could obtain a satisfactory result from nitro glycerine The form of nitro glycerine that I used were the elegant tablets of Fraser, so much more convenient than the alcoholic solution

Dr W L Axford I have here the

SAC OF AN ANEURISM OF THE LEG,

not very large or elaborate, but interesting because of its locality and the history of the case Some time last fall, along in November, a Bohemian came to the South Side Dispensary, having a little lump about as large as a walnut just above the internal malleolus I could not get his history, as he could not talk English, all that I could make out was that it had been growing there about a year, and pained

him some The skin was natural over the growth, which felt soft and fluctuated I made up my mind that it was some kind of a cyst, and advised him to have it excised On cutting down upon the growth I found at once that I had made a mistake, from the color of the sac, which was blue One of my assistants said he saw a little artery spurt I stitched up the wound and found I had excised the sac of an aneurism It was about the size of a walnut when fresh This case was peculiar, as there were none of the usual symptoms of aneurism, it was also peculiar in the large size of the sac compared with the size of the artery The patient made an uninterrupted recovery

Dr Jones, of Pittsburg, Pa I heard only a portion of the discussion on the subject of angina pectoris One symptom I will mention as having occurred in my own experience, that I believe is not mentioned in any of the literature that I am familiar with In acute attacks of angina there is a feeling of constriction that may be relieved by firm pressure against a sharp body, such as the back of a chair or the edge of a table, that feeling of a patient wanting to press against some sharp substance, the back of a chair or the edge of a table, has been invariably present in all of the cases that I have seen, and I do not know that it is mentioned anywhere The use of nitro glycerine and amyl nitrite I would suppose would hardly be proper in chronic cases, on account of the danger spoken of, the danger of sudden cessation of the heart's action from paralysis or failure

Dr Lagree, *of Charleston*, S C, mentioned some

PECULIAR SYMPTOMS CAUSED BY EARTHQUAKES

The earthquake in Charleston, with us, is a thing of the past There were some peculiar features produced by the earthquake, from a medical point of view One of the most common conditions was an obstinate nausea, and in treating these cases we found the only remedy that would give any satisfactory result was muriate of cocaine Another condition we found was falling off of the hair in patches, especially among the ladies I have had three cases in which the hair gradually fell out in patches, which I attributed to nervous shock Fortunately the hair was generally saved Those were the most prominent symptoms produced by the earthquake

---

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, May 4, 1887

The President, Jos Taber Johnson, M D, in the Chair

Dr J Ford Thompson exhibited the specimen and gave the history of a case of

COCKLE BUR REMOVED BY TRACHEOTOMY FROM THE LARYNX

(See p 432)

Dr S C Busey said that Dr Thompson had confined himself to the removal of a cockle bur, but that Dr Weist had published an article in which he discussed the removal of all kinds of foreign bodies from the larynx, and had collected the published cases Some years ago he was called to see the 12-year old daughter of a physician Her father was not certain of the cause of the pain over the left bronchus, the cough, fever and loss of appetite, expectoration and emaciation which was present, although the girl stated that she had swallowed a "cockle bur" Dr Busey saw her when she had been sick about ten days He could not find any cause for the symptoms She complained for about six months, when she coughed up the bur The symptoms disappeared and she has not had any trouble since

Dr C E Hagner expressed his mortification that his attempts to remove the bur in the case reported had been unsuccessful He saw it above the false vocal cords, introduced the forceps and felt them strike it It was covered with mucus, and the forceps, instead of grasping it, slipped and pushed it out of sight He then gave up the search The following morning he again examined the patient, but the larynx was full of mucus and pus so that he could not see the bur at all He agreed with Dr Thompson that exploration with the finger is advisable He thought it better first to anæsthetize the patient and try the forceps If not successful with them then tracheotomy is called for The patient referred to by Dr Busey had frequent hæmorrhages in addition to the symptoms already mentioned He had a case some years ago of a man who had frequent violent paroxysms of coughing and great dyspnœa Very little air entered the left lung Some time afterwards, while the man was climbing a steep hill, he was seized with a violent fit of coughing and expelled a grain of oats, from the oatmeal he had eaten, which was covered with mucus and was as large as a marble

Dr E Carroll Morgan said that he was much interested in the history of Dr Thompson's case, and congratulated him upon its happy termination He was also pleased to learn that recourse was had to the laryngoscope, which is indeed to day an indispensable, as well as a ready, means for the recognition and extraction of foreign bodies in the air passages On the other hand, however, he regretted that in this particular patient the cockle bur was not extractable by laryngoscopal methods Since the introduction of the laryngoscope, operations for the removal of foreign bodies from the larynx by means of artificial openings have notably diminished One of the most striking instances in which the value of this instrument in diagnosis was demonstrated occurred in 1876, in the experience of Dr Samuel Johnston, then of London, but at present a practitioner in Baltimore, Md The history of his case is briefly as follows

A nervous boy of 14, living in Wisbeach, was suddenly seized during the night with suffocation and a feeling as if there was something sticking in his windpipe The family were aroused and a physician sent for The boy continued to suffer during the night from pain and difficulty of breathing In the morning, as there was no improvement in his symptoms,

the attending physician performed tracheotomy and put in a tube The breathing improved, but an attempt being made to dispense with the canula, dyspnœa immediately followed and the tube had to be replaced The boy was then sent to London, when, upon laryngoscopic examination, a small toy locomotive was found firmly wedged in his larynx, and was partly covered by a web which held it firmly in position It was found impossible to remove the foreign body through the natural passages, and the wound which had been made for the previous tracheotomy was therefore enlarged through the cricoid cartilage, crico-thyroid membrane and thyroid cartilage, when the locomotive came into view and was easily extracted The patient left the hospital with a good voice It is worthy of remark that in this case the toy locomotive was not suspected until detected by laryngoscopic examination, when the boy admitted having had such a toy in his mouth four months before

A case has recently been recorded by Dr D B Crawley, of Mississippi, in which a cockle-bur recognizable by digital exploration was extracted from the larynx of a negro aged 9, by the ingenious method of twisting cotton on the end of the index finger and rotating it in the larynx over the bur in such a manner as to fasten the prickles to the cotton Dr Thompson did not mention this case in his list, although he (Dr M) had just been told that the same expedient was unsuccessfully tried on the boy Dr Thorner succeeded in extracting an impacted cockle-bur from the larynx of a boy of 15 by means of a sponge instrument guided by a laryngoscope

During the past ten years he (Dr H) had extracted numerous foreign bodies from the larynx through the natural passages, the most curious of them being

A PIN WHICH HAD REMAINED IN THE LARYNX THREE WEEKS

The patient was a woman, aged 30, referred to him a year since, by Dr J W Bayne She stated that whilst holding a number of pins in her mouth three weeks before that one had been swallowed Since that time her sufferings had been very great, and there was almost complete inability to swallow food or to talk above a whisper The larynx on the right side, externally, was much swollen, and the patient in a nervous and debilitated condition Various unsuccessful attempts had been made in Maryland, from whence the patient came, to extract the pin, when, upon her arrival in Washington, she was immediately sent to him by Dr Bayne Repeated laryngoscopic examinations under cocaine anæsthesia revealed the presence of a pin which transfixed the right ary epiglottic fold, the point of the pin looking inwards and downwards towards the left vocal band, its head being in the upper portion of the fossa pyriformis, from whence, after many trials, it was ultimately withdrawn by means of Mackenzie's antero posterior forceps The pin was greatly rusted, and is herewith presented to you for inspection This patient made a rapid recovery, although there was laceration and swelling of the lower pharynx and interior of the larynx

Regarding digital exploration of the larynx and its easy performance, to which Dr Thompson has called attention, he would say that it is of great value and readily accomplished, especially in children The finger is a valuable aid in practicing O'Dwyer's method of intubating the larynx, and enables us to prevent the tube from slipping out of the larynx whilst we are withdrawing the safety string Dr Morgan had intubated one child 22 months old for laryngeal diphtheria early in December last, a brief allusion to which was published in the *Maryland Medical Journal*, December 25, 1886 This child died about 18 hours after intubation, and this is perhaps the reason the Society has not heard more of this his first, and unsuccessful, case of laryngeal tubage

DR J FORD THOMPSON had intentionally excluded the removal of everything but cockle bur There are numerous cases of foreign bodies having been removed from the larynx Ashurst goes over the whole subject in his last work In this case he had passed a large catheter and a large pair of forceps upwards through the tracheal wound, but the finger proved more effective This use of the finger is the most interesting feature, and he has not been able to find a similar case reported

(*To be concluded*)

CHICAGO GYNÆCOLOGICAL SOCIETY

Regular Meeting, Friday, April 15, 1887

THE PRESIDENT, CHAS WARRINGTON EARLE, M D, IN THE CHAIR

DR H T BYFORD presented the

ROUND LIGAMENTS FROM A CASE OF ALEXANDER'S OPERATION

I have here a specimen of the round ligament, removed by the Alexander operation only a few hours ago They are interesting on account of the extreme attenuation, which may account for some cases of failure in this operation They are almost as thin as wrapping cords, and will give quite an idea of what some of these ligaments are after they are stripped of their fibrous coat and drawn out In one operation which I performed there was just such a condition, and after a long careful attempt to make them run, I broke one of them and almost lost it The other one I could not get entirely loose, and only shortened it three quarters of an inch I met with one ligament twice the normal diameter, or over four times the diameter of this one, the opposite ligament in that case was about as thin as this one I have performed Alexander's operation six times

DR C W EARLE exhibited a

CYSTIC SARCOMA OF RIGHT OVARY

DR CHRISTIAN FENGER exhibited a

PROLIFERATING CYSTOMA WITH PARTIAL INTRALIGAMENTOUS DEVELOPMENT

In addition to my remarks on parovarian cysts, at a former meeting of this society, I wish to present a

specimen of a proliferating cystoma with partial intraligamentous or retroperitoneal development It was taken from a woman, 48 years old, operated upon March 22, 1887, in the Emergency Hospital The tumor was of enormous size The abdomen measured at the umbilicus 132 cm in circumference, and from the xiphoid process to the symphysis pubis 63 cm When, after tapping, the cyst was partially brought out of the wound, I found a very peculiar formation attached to the side of the cyst near the abdominal end of the enlarged Fallopian tube As will be seen in the specimen passed around, it consists of a long, narrow cylindrical sac, 21 cm long and 4 cm in diameter Its wall is almost transparent and half filled with a clear fluid I have not been able to find described anywhere in the literature a similar appendix to any ovarian cyst It seems to me likely to be a reopened and dilated Morgagnian hydatid, the remnant of the terminal portion of Muller's duct The retroperitoneal portion of the cystoma was enucleated as usual, leaving the large wound cavity with insufficient peritoneal covering In this cavity Miculicz's drain was used with a glass tube through its center The last of the drain was removed on the eighteenth day, and the wound finally closed shortly afterward

DR W H BYFORD I suppose there are very few instances of parovarian tumors in which they become pedunculated We do infrequently meet with instances where there is a fair pedicle, but they are exceptions to the rule, which is that they rise from within the broad ligament, and often carry up with them a layer of fibrous tissue And instead of being pedunculated, they commonly lie in a cup-shaped excavation in the broad ligament, extending down into the ligament some distance There is therefore generally no way of getting rid of them except by enucleation As was stated by Dr Fenger at our last meeting, the general subject of enucleation was probably taught to Americans at least, by Dr Miner, of Buffalo But at the time Dr Miner wrote upon the subject we did not possess the same knowledge of the difference between broad ligament tumors and ovarian tumors that we now have At that time we frequently confounded ovarian tumors with tumors of the broad ligament, and Dr Miner did not confine himself to the consideration of this sort of tumor, but believed he was always enucleating a cystoma of the ovary when he removed a cyst from the abdominal cavity We are now disposed to believe that most, if not all his cases (he did not enucleate many) belonged to the variety of parovarian cysts It is with the view of pointing out a few things in connection with the enucleation that I am now speaking In practicing enucleation, as we have done heretofore, we make every effort, without much method, to get rid of the fibrous covering by tearing it off, without any special reference to the exact manner in which it is done

I have met with a few of these tumors in the last three or four years, which has caused me to think differently on this subject, and made me to look more narrowly into the matter of enucleating them About four years ago I was called upon to operate in a case of this kind, in which there was considerable inflammation as well as a very thick coat of fibrous substance brought up with the upper layer of the broad ligament, enveloping the lower third of the tumor quite closely In operating I found that by careful manipulation I could get out the cyst proper from the capsule without tearing down the side of it The manipulation consisted in pushing the fingers down deep between the capsule and the cyst until they went below the tumor on all sides and in the centre, when I found that I could get the sac entirely out, and in that instance succeeded in removing it without at all tearing down the sides of the enveloping capsule I could then bring the edges of this cup shaped stump to the external wound and stitch them to it By means of a drainage tube in this cavity passing through the external wound, I was able to drain of the fluid, while the whole raw surface of the hollow stump was excluded from the peritoneal cavity I have done that operation myself now three times, and have seen it performed twice Two weeks ago last Sunday I saw an operation at the Woman's Hospital, performed by Dr Henry T Byford, for removal of one of these broad ligament tumors After emptying the sac with the trocar, so that it was relaxed, he lifted it up as high as he could with Nélaton's forceps, then took the knife and lightly cut through the fibrous covering until he could get his fingers through it, when it was enucleated as above described The inside of the cup-shaped pedicle or stump was entirely excluded from the peritoneal cavity, its edges were brought up to and included in the external wound, and then a drainage tube introduced This method of operating is always satisfactory, as, by making a perfectly close cup, the sides do not permit of the blood or serum getting into the peritoneal cavity In two cases we found that no discharge came through the tube, hence it is probably not always necessary to drain A remarkable thing in connection with the operations is that there is very little bleeding In Dr H T Byford's case the patient is convalescent, almost ready to go home, she lost less than 4 ounces of blood in the whole operation There was no ligature placed upon any of the vessels

DR FENGER spoke of the operation being somewhat dangerous on account of the intestines In this case the cæcum and the vermiform process were plainly visible upon the side of the tumor, but the fingers hulled out the capsule upon which they lay and left them perfectly free I am convinced that these tumors can be cured as a general rule much more easily than by enucleation I have not tried the process upon large tumors, but in small ones I make an incision through the abdominal walls, evacuate the tumor and leave a drainage tube in the sac In four instances I have seen them cured in this way These cysts are so simple in structure and have so little vitality that it is only necessary to drain them Even tapping or aspirating them is sometimes sufficient No dangers have arisen during the convalescence, and I am in hopes that the treatment of parovarian tumors on further experience will be very much simplified I fully be-

lieve that evacuation and drainage of large parovarian cysts would be quite as successful as in the smaller ones

A NEW COLPOPLASTIC OPERATION FOR DEFECT OF THE VAGINA

When I saw the patient the external genitals were normal, and immediately inside of the labia minora there was a cicatricial mass, funnel shaped, and in the centre of it an opening through which only a very fine probe would pass Examination of the rectum showed, about 3 inches inside of the external genitals, a tumor which I believed was the uterus, but when I came to operate I found it to be a sac filled with blood and mucus—a sac the size of a hen's-egg, and behind that a small uterus This dilated sac was at the upper portion of the vagina, and the lower 2½ to 3 inches of the vagina was a cicatricial mass I made the usual operation recommended under these circumstances, dilatation with partial excision of the cicatricial tissue, dilatation with blunt instruments between the rectum and bladder In that way we can get a vagina of any size without much trouble, a space large enough for a child to pass through, but we know that it is very difficult to keep such an artificial vagina from retracting In this case, as soon as the glass plug was left out for a few days, the vagina retracted so as to barely permit the passage of the finger It is natural that here, as in other places of the body, we should want a covering of skin and mucous membrane to keep such a channel open

Heppner, of St Petersburgh, in 1872, proposed to operate for absence of the vagina, at the same time dislodging the menstrual blood accumulated, then planting in a flap from the peritoneum The posterior lines of the H were prolonged so as to loosen the flap sufficiently to put it some distance into the artificial vagina Credé, in 1883, had evidently not seen this article Nobody seems to have imitated or adopted this method, because Credé describes a method of operating in an obstinate case that had been operated upon over and over again with usual dilatation method, and in which the vagina always retracted so as to cause the patient great inconvenience in her menstruation He operated by dilating the vagina as usual, then he took a flap consisting of one labium majus, leaving the labia minora, and planted that in the posterior surface of this new vagina He states that the hairs on this labium majus did not cause any inconvenience It was an elderly lady, over 50 years of age, where marriage was out of the question, she only wanted relief from her menstrual troubles In this case I thought it would be better to use the labium minora for a flap on each side, the labium minus, when reasonably well developed, being capable of folding and unfolding, and consequently the flap acquires the diameter of such labia minora By unfolding them we get one inch more By loosening the labia minora on the sides, leaving them in connection with the skin at the posterior side of the entrance to the vagina, and then unfolding them, I get a flap 3 inches long and an inch in diameter, although this labium minus looked very thin, almost transparent, so that I thought it would die off when planted in It did not have the advantage of being mucous membrane, but was without hairs The result was that both of the flaps healed I have the patient here, so that the Fellows of the Society can see that the vagina is almost perfect The loss of substance caused by taking the flap is very easily covered by drawing together all the skin It is very movable, so that there is really no loss of substance A flap of skin 1½ inch broad is very easily covered by drawing the neighboring skin together So far as after-treatment is concerned, there has been no difficulty In the beginning the vagina was packed with iodoform gauze, and later glass plugs were introduced

ANTISEPSIS IN ABDOMINAL OPERATIONS, SYNOPSIS OF A SERIES OF BACTERIOLOGICAL STUDIES

(Preliminary Note, by Christian Fenger and Bayard Holmes)

Synopsis of a Series of Bacteriological Studies—These investigations were undertaken to determine how far the necessary aseptic conditions had been secured and maintained in the abdominal sections performed by Dr Christian Fenger One case of another operator is brought in to compare less thorough antiseptic precautions

In order to estimate the results of these researches, you must know what preparations were made for the operation on the part of each concerned

The Preparation of the Operating-Room—In the Emergency Hospital and in the County Hospital, the walls and the floor and all the furniture were thoroughly washed with a 1–1,000 sublimate solution on the day before the operation The cracks about the windows and doors were stuffed with cotton, and the room closed to every one except the nurse that made the preparations

To test the condition of the atmosphere in this room, in the Emergency Hospital, four plates of gelatin were exposed for 48 hours on the operating table, August 24 and 25, 1886 After six days' incubation in the moist chamber, from eight to twelve colonies of all kinds appeared on each square inch of surface Most of these were moulds, which grew very rapidly, some were micrococci and some bacilli As less than twelve colonies developed to the square inch, it is probable if the plates were exposed only an hour instead of 48 hours, not more than one colony would be found on each four square inches So that the danger of atmospheric infection from falling germs would be very slight under similar conditions The danger would be, no doubt, increased by the movements of the assistants, and the increased circulation of air through the difference in temperature of the external and internal atmosphere when the room was in use

The Preparations of the Operator and Assistants—Each took a sublimate bath (1-2000) and put on sterilized cotton suits The hands and arms were then washed 5 minutes with warm water and green soap, and scrubbed with a brush, and then washed half a minute in a 1-1000 sublimate solution The patient received substantially the same treatment

FOREIGN CORRESPONDENCE

LETTER FROM LONDON

(FROM OUR OWN CORRESPONDENT)

Treatment of Inveterate Neuralgia—Apothecaries and Medicine—Phenol Mercury

Mr Victor Horsley has recently drawn attention to some cases of *Inveterate Neuralgia* which have been under treatment by him He gave a short history of three cases of this distressing malady which he had treated with apparent success by avulsion of the fifth nerve All three of his cases had come under his observation at a very late stage of the affection, the shortest period being three years and a half after the outset of the mischief, and in one case as much as seven years after All were practically edentulous when they came to him, and from all of them after the operation he had the same story, namely, gratification at being relieved from pain, and regret at the loss of so many sound and useful teeth Were there no indications by which it was possible to diagnose pain which was due to mischief somewhere along the trunk of the nerve from that which was due to disease of the teeth? If this could only be done with certainty it would mark an important advance in dealing with these often terrible cases of long suffering Pain referred to one of the branches of the fifth nerve might be due to mischief of cerebral origin, to irritation along the trunk of the nerve, or at its peripheral extremity He did not dwell on the possibility of the pain being due to intra cranial mischief, since the general rules applicable to this class of cases would generally suffice for the discovery of the seat of trouble The diagnosis between some affections of the trunk of the nerve and of its peripheral termination was not so easy, but judging from his own experience, he thought there were two points which might assist in forming a decision A very valuable indication of mischief in the trunk of the nerve, were trophic changes when present Thus in one of his cases, the lower lip was greatly swollen, the skin being glazed and excessively sensitive, or the vessels might be at one time dilated and at another just the opposite Wasting of the muscles was another evidence of the same kind Certain abnormal conditions of sensation were also valuable In an ordinary case of toothache all the branches of the fifth nerve might seem to be affected but in cases where the disease was in the trunk of the nerve, the skin might be hyperæsthetic at one place and anæsthetic at another

Another characteristic form of hyperæsthesia was that in which gently touching the skin caused extreme pain, whilst firm pressure caused no pain at all As to the apparent origin of the pain, he found that in most cases the patient said it began in the teeth, but in some cases it was said to begin in the bone and in the skin If the pain was referred primarily to the teeth, it might be due to them, or it might not, but if it began in the bone or skin and only affected the teeth subsequently, he thought it might be inferred that the disease was in the trunk of the nerve If, again, in addition to severe pain over the area of distribution of the nerve, distinctly tender spots were met with along the course of its branches, this was generally an indication that the whole nerve was in a state of irritation, but a somewhat similar condition sometimes might be met with as a result of peripheral irritation If the pain was brought on more commonly by movement, this seemed to indicate affection of the nerve trunk All his cases stated that opening the jaw to eat or talk brought on pain, and so far as he was aware, the effect of movement in causing pain was not so marked in cases where this loss was due to peripheral irritation With regard to treatment, any cases of dental irritation should be removed, and in some this would effect a cure Drugs invariably failed sooner or later Nerve stretching should not be performed on the fifth, for although it gave relief for a time, the pain invariably recurred Avulsion, performed close to the aperture of exit from the skull as possible, generally cured, the success of the operation seeming to depend greatly on success in obtaining primary union, and the removal of the nerve was not followed by any trophic changes in the parts supplied by it

At a recent meeting of the General Medical Council, in which the right and wishes of the Apothecaries' Society was under discussion, Sir William Gull contended that it was not desirable to have a Society of Apothecaries at all, and that its existence was contrary to the interests of medicine People he said did not get well by drugs When the Prince of Wales was ill of typhoid fever, how many doses of medicine did he take? Not four The question was, whether the profession should be set free from the trammels of the past Medicine was once given even for fractures It was the powers of nature that effected the cure of disease, and the duty of the medical men was not to give drugs, but to see that nature's powers were not interfered with

Since the time of Paracelsus, when the antiseptic properties of mercury first came to light, mercurial preparations have been more or less in vogue throughout the world A new compound of this description, which may possibly attract a good deal of attention, is called phenol-mercury It is produced by mixing an aqueous solution of 132 parts of phenol potassium with a solution of 271 parts of mercuric chloride, when a reddish orange precipitate is thrown down This is washed on a filter until the filtrate no longer gives a reddish color on the addition of iodide of potassium In drying the product its color becomes brighter and the dry powder retains only a slight odor of carbolic acid Phenol-mercury is given in pills containing 0 02 grams, of which the dose is 2 a day at first, gradually increased six daily

DOMESTIC CORRESPONDENCE

HEART WOUNDS

Dear Sir —Believing with Dr Arthur Young, who writes for THE JOURNAL of Sept 13 concerning the "Burton Case," that cumulative testimony is of more importance than speculation as to the capacity for

action after heart wounds, I beg leave to submit the following facts in an accidental killing The fifteen years old son of H Bruaw, of this place, was found dead near the railroad track on the afternoon of Aug 9, 1886 It was at first supposed he had been killed by the cars, but on removal to the house and stripping, a hole of considerable size was found about midway between the left nipple and sternum It was then supposed he had been shot, and a vicious neighbor boy who had threatened the family was arrested On arrival of the coroner, and with the assistance of Dr Wm Thompson, I made an examination We found the missile (the character of which was unknown) had fractured two ribs in passing in, and on enlarging the opening and introducing my hand, I found a corresponding opening in the pericardium which was full of blood, and a stellate laceration in the front wall of the left ventricle, through which I extracted from the cavity of the ventricle a crumpled piece of tin ¾×½ inch in size This cleared up the mystery Subsequent investigation showed that the boy had found an open package of signal torpedoes, used to stop trains at night and at other times, left there by track repairers, and near by some bolts and an old rail which they had removed Stooping down he had laid a torpedo on the rail and striking it with the bolt head, it had exploded, driving the piece of tin into his heart He must have then risen to his feet and run or walked in the direction of his home at least thirty steps, crossing to the opposite side of the track before he fell on his face, dead Dr Young's case was a knife incision, which would not have emptied the ventricle as promptly as this torn opening Might it not be possible, then, that a would be suicide could shoot himself through the heart, then, uncertain of the result, make the second attempt? or in other words, ignoring the direction of the shot in the "Burton Case," would not other evidence than that the first shot was through the heart be needed to determine between homicide and suicide?

HERBERT C JONES, M D

Cerro Gordo, Ill, Sept 21, 1887

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

Summer Charitable Work for Poor Children—Meeting of the American Gynæcological Society—College of Physicians and Surgeons in the New Buildings and Preliminary Requirements—Death of Dr Alonzo Clark

The various charitable societies have now brought their summer work among the children of the poor to a close During the season just ended the St John's Guild have received some $12,000 for the support of the free excursions of its floating hospital, and as the total expense of a single excursion, including food for the mothers and children, does not exceed $250, it will be seen that the Guild has been enabled to accomplish much good during the heated term Dr Moreau Morris, Chief Sanitary Inspector, who has had the direction of the summer corps of physicians of the Board of Health this year, has written a letter to Mr Faure, Secretary of the Guild, in which he extols the results obtained in the restoration to health and saving of life among sick children by the trips upon the floating hospital One has but to visit the barge, he says, to become convinced of the value of these excursions, and the gathering of nearly a thousand enfeebled children strikingly reveals the sufferings of the little ones caused by the close and unwholesome atmosphere of the tenement houses where they live and their improper and insufficient food There is no danger of contagion on the trips, as every child is subjected to a rigid scrutiny by the examining physicians before it is allowed upon the boat The absence of all sectarianism, as regards creed or race, in the dispensation of this charity, Dr Morris continues, commends it to all classes, and in the caring for these afflicted children by the summer corps, supplemented by these fresh air excursions and liberal and judicious feeding, no nobler application of Christian charity could be desired As an illustration of the great good resulting from the excursions he refers to an instance which came under his observation on the occasion of an official visit to the floating hospital in the early part of August, in which an infant was carried on board almost moribund, to return from the invigorating trip down the Bay with a new lease of life During the past season the St John's Guild has added to its charitable work a useful feature in giving some special free excursions for "debilitated, feeble, and worn out convalescent adults"

The Summer Home at Bath and the Health Home on Coney Island of the Children's Aid Society were closed for the season on the 10th of September At the former 4,436 poor children from the tenement districts of the city were received, and of these over 3,000 little girls spent a week, while at the latter 4,602 mothers and sick infants had the benefit of the day excursions, and 753 mothers, with 1,448 children, remained for a week The total number at both homes was 11,239

The twelfth annual meeting of the American Gynæcological Society, which was held at the hall of the New York Academy of Medicine September 13, 14 and 15, was marked by the attendance of a number of distinguished foreigners who had come from the International Medical Congress at Washington, and among these were Drs Grailey Hewitt and George Granville Bantock, of London, A R Simpson, of Edinburgh, August Martin, of Berlin, A Cowles, of Genoa, and G Apostoli and A Doléris, of Paris. On the evening preceding the meeting Dr Paul F Mundé entertained these gentlemen, with a number of American guests, at an elaborate dinner at the Union League Club, and after the adjournment on the third day the Society had its annual dinner at Delmonico's, while on Tuesday evening, September 13, Dr Fordyce Barker gave a handsome reception at his residence to the American Gynæcological Society, its distinguished foreign guests, the Obstetrical Society of New York, and the members of the Obstetric Section of the New York Academy of Medicine

On the 2d of October the College of Physicians

and Surgeons will commence its first session in the magnificent new buildings provided by the liberality of the late Mr Wm H Vanderbilt and his family, and the announcement is made that while no preliminary examinations will be required for the session of 1887–8, for the session of 1888–9, and thereafter, applicants for matriculation will for the first time at this College be required to undergo examinations for the admission, with the exception of those, 1, who shall declare themselves not to be candidates for the degree of M D from the College, 2, who shall present certificates of having been successful at examinations for admission to the School of Arts or School of Mines of Columbia College, of which the College of Physicians and Surgeons is the medical department, 3, who shall present diplomas or certificates of graduation in arts, philosophy, science, or medicine, from recognized colleges and schools of science, 4, who shall present certificates from recognized colleges or schools of science, to the effect that they have studied satisfactorily any or all of the subjects required for admission to the College, in which case they will be admitted without examination in the subjects so certified to The examinations for admission are to be in writing, and will include English composition, sufficient Latin for the translation and parsing of Cæsar or Sallust, algebra, as far as simple equations, and the first book of Wentworth's Geometry, or its equivalent The examinations are to be held semi-annually, and an applicant rejected or conditioned in any branch or branches will be eligible for reexamination at any subsequent semi-annual examination

In the death of Dr Alonzo Clark New York medicine loses one of its most illustrious exponents, although the State of the venerable professor's health has for some time past necessitated his complete retirement from professional work Dr Clark felt a deep interest in the "Code question" which agitated the profession here a few years ago, and was in hearty sympathy with the movement which resulted in the organization of the now powerful and prosperous State Association, but his enfeebled condition prevented him from taking any active part in the struggle

NECROLOGY

WILLIAM H THORNDIKE, M D

William H Thorndike, M D, born at Salem, Mass, died at Boston, Dec 26, 1884, aged 60 His death has left a large void in the medical profession of Boston, exemplified so well for thirty five years the life of a good physician that it is difficult to do his character justice in an obituary notice Modest in bearing, Saxon in speech, reticent of many words, his calm judgment, clear perception, and entire honesty commended him to the confidence alike of friends and patients He was the type of unselfish devotion to his calling He pursued medicine as a profession, and not as a trade Too careless, perhaps, of pecuniary returns, he lived in his cases, gave himself wholly to his sick, and was death struck while attending a professional call He was an active and valued member of the various medical organizations, including that of the American Medical Association since 1865

Beginning to practice in a somewhat isolated community at East Boston, he early learned to rely wholly on himself, and never hesitated to undertake anything he was called on to do Thus was developed a peculiar roundness and completeness of character usually found only in a country doctor To this he added the wide experience and versatility generated in great cities, and both were concentrated and widened by seventeen years' service as surgeon of a great hospital All departments of medicine and surgery, many of which are now confined to specialists, he practiced without hesitation and with success

He belonged to the older school of surgeons Natural taste, acquired dexterity, and long practice, had made a deft, intrepid and successful operator He loved his art With him to see clear was to do Diagnosis was followed by action Expectation in surgery he well recognized as of less value than in medicine For twenty years, both in private practice and in the hospital, he did an enormous number of operations, surgical gynecological, obstetrical, ophthalmic An enumeration would be tedious, and we will allude only to the unusual ones He tied the internal iliac artery, behind the peritoneum, for secondary hæmorrhage from a perforating wound, and the patient lived to attend the funeral of his surgeon He tied the external iliac vein for primary hæmorrhage from a stab with success He tied the gluteal artery at its emergence from the sciatic notch for a traumatic aneurism in the nates. In this he boldly performed the operation described by Bell, who so graphically describes the rush of blood and clots and the difficulty of seizing the vessel He removed a cobble-stone, 5 inches by 3, and weighing 2 pounds, from the peritoneal cavity with success In this remarkable case the patient had inserted the stone into his rectum, thence it had ulcerated through the rectum and colon into to the peritoneum Dr Thorndike passed his hand into the rectum, but the stone escaped beyond his reach He then opened the peritoneal cavity by an incision 5 inches long, parallel to the rectus muscle, and removed the stone The patient recovered He opened the gall-bladder, and removed calculi by incision

Among the surgical feats he prized the most were two operations for evacuating pus from a retro peritoneal abscess near the cæcum The symptoms in the first case were constitutional more than local, but very intense He made the incision to tie the iliac artery, pushed back the peritoneum, found a mass of induration in the iliac fossa, plunged in a trocar, and was rewarded by evacuating pus, and the perfect recovery of his patient Most of these operations were done before the days of antiseptic surgery The removal of Meckel's ganglion for neuralgia, amputation at the hip joint, many lithotomies, Cock's operation for perineal section—which he valued highly—many large tumors, might be added to this list He also

had practiced every operation of modern gynecology except Battey's operation

A large, continuous, and exacting private practice gradually wore him out, but his constitution was also sapped by a poisoned wound received three years before his death He sank rapidly under a double pneumonia, and died in forty-three hours from the primary chill, apparently unconscious of suffering

D W C

HENRY M SAVILLE, M D

Henry M Saville, M D, was born in Quincy, Mass, July 29, 1833 Graduated from Amherst College in 1855 He commenced the study of medicine at Dartmouth College, taking his second course at Harvard Medical College, and graduating from the University of Pennsylvania in 1857, joining the Massachusetts Medical Society in 1858, and the American Medical Association the same year He at once commenced practicing medicine in his native town, and was eminently successful In April, 1861, he was made surgeon of Fourth Mass Infantry, accompanying it to Fortress Monroe, was at the battle of Big Bethel and returned home after a three months' volunteer service He married in 1862, and moved from Quincy to Boston, where he practiced for ten years His health failing in 1872, he was obliged to seek a warmer climate, spending one winter in Egypt, visiting California, passing several winters in Florida, with so much benefit that he again tried a Northern winter, located in New York, where he died Jan 11, 1881, of pneumonia

M G P

LUTHER PARKS, M D

Luther Parks, A M, M D, whose death was previously announced, was born in Boston, Nov 4, 1823, and graduated at Harvard College in 1843, taking high rank in a class which included many men who have become distinguished Dr Parks took his degree of M D in 1847, and in the same year went to Ireland as surgeon of the U S Sloop of War "Jamestown," which was sent, loaded with provisions, to relieve the starving Irish people He was there made a Fellow of the Royal College of Surgeons of Ireland After his return he married Miss Julia Dale, and established himself at the South end of Boston In his active practice there of eleven years, during a portion of which he served as one of the District physicians of the Boston Dispensary, he was notable for conscientious fidelity and kindness toward his patients, and for his skill as an obstetrician, which he took pains to perfect, by practical work at the Rotunda Lying in Hospital at Dublin, during a second visit to Europe in 1852 After the death of Mrs Parks, in 1859, he again went abroad, everywhere interesting himself in what was being done in the profession

Dr Parks married in 1861 Miss Catharine Burroughs, and, at the request of his father who was advancing in years, he removed to Chestnut street and retired from active practice During the late war, at the solicitation of Governor Andrew, who was a personal friend, he went to the peninsular of Yorktown as a volunteer surgeon After his father's death, Dr Parks again went, in 1872, to Europe, residing there until his death at Pau, Nov 19, 1886, aged 62

Dr Parks was for some years one of the physicians of the Boston Lying-in Hospital, and was associated with Dr S L Abbot, as editor of the *Medical and Surgical Journal* At the annual dinner of the Massachusetts Medical Society in 1871 he presided as Anniversary Chairman As Chairman of a Committee of that Society he carefully investigated and reported upon an epidemic of cerebro-spinal meningitis in Massachusetts He joined the American Medical Association in 1849 attending in 1855 and 1865

THE PROSTATE GLAND

A Review of its Anatomy, Pathology, and Treatment

Read in the Section on Surgery and Anatomy, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY A H WILSON, M D, M R C S (ENG), OF BOSTON, MASS

The importance to the genito-urinary surgeon of a due appreciation of the pathological changes underlying a sound system of therapeutics, of that portion of the urinary canal called the posterior or prostatic urethra, and surrounded by that composite body called the prostate gland, must be my apology for entering into a consideration of its minute anatomy with considerable detail

Anatomy.—The prostate gland, or more properly speaking the prostate muscle, is a composite organ composed of unstriped muscular, fibrous, elastic, connective, glandular, nerve, vascular, lymphatic, and a small amount of striped muscular tissue It resembles a truncated cone in shape, its base surrounding the neck of the bladder, its apex terminating at the membranous urethra, from which it is separated by the posterior or deep layer of the triangular fascia or triangular ligament Its position in the erect posture of the body is obliquely downwards and forwards It is placed just below and behind the lower border of the symphysis pubis, and distant from the same from three- to five eighths of an inch, the intervening space being occupied by fascial cellular and muscular tissues It rests upon the second portion and the junction of the second and third portions of the rectum From a series of fifty-three healthy adult prostates examined by Sir Henry Thompson, he makes the measurements as follows From base to apex, from 1 3 to 1 8 inches, measurement most commonly found, 1 4 inches, the greatest transverse measurement near base, from 1 4 to 2 inches, measurement most commonly met with was 1 75 inches, the point of extreme thickness ranged between 55 and 95 inches, measurement most commonly met with was about 7 of an inch The measurements given by Dupuytren are considerably larger, who believed the prostate to measure from 20 to 24 lines transversely, and to be 10 or 12 lines in thickness, and upon these estimates his calculations for the operation of bi lateral lithotomy were based Deschamps, Senn, Gross, and Hodgdon, all of whom made practical researches relative to the size of the prostate, practically agree with Thompson, whose conclusions, I think, we may safely accept as the average size of the normal prostate The weight of the adult normal prostate may be placed at from 4 to 6 drachms This accords with the conclusions of Thompson, also those of Dr Messer, of the Royal Naval Hospital, who dissected 100 prostates, 45 are classed as normal in size and average in weight, 4 drachms and 57 grains

The prostate consists of two lateral, symmetrical lobes, each of which is somewhat pointed anteriorly and terminate posteriorly in rounded extremities which, projecting somewhat, present an angular interval or notch between them These two lobes are united by two intermediate masses, one of which is placed in front of the urethra, and consists of muscular and connective tissue, and is called the anterior commissure or isthmus The other is placed behind the urethra, and lying between the posterior borders of the lateral lobes their whole length consists of a stratum of unstriped muscular, glandular, and connective tissue, thin and narrow in front, but posteriorly this stratum becomes thicker and sometimes has a rounded form, as if it were an independent formation The anterior or thin portion of this structure has received the names of the posterior isthmus or commissure, while the posterior rounded extremity or base has received the appellation of the third or middle lobe of the prostate, the propriety of which appellation Sir Henry Thompson calls in question Sir Everard Home appears to have first conceived the idea that the portion of the posterior connecting band of prostatic tissue which forms a rounded and thickened border should be classed as an independent lobe, and this idea has been accepted by most English anatomists The position of Thompson, that in the normal prostate there is no portion of the central connecting mass of prostatic tissue, which presents sufficiently the appearance of an independent formation to entitle it to the appellation of the third or median lobe, is also taken by Cruveilhier, and by most of the French anatomists Cruveilhier expresses the general opinion of French observers when he says that the ejaculatory ducts being received into a groove or channel in the substance of the prostate, a portion of variable size is indicated by them, but that it has no title to be called a lobe It is not, he says, an iso

lated piece, and should be called the median portion If we retain the term lateral lobes, we apply to the part anterior to the urethra the term anterior commissure, a part which is about one inch in length, and the term posterior commissure to that which corresponds to it for the same length behind the urethra, it leaves that thicker portion of the organ which lies behind the veru montanum, which is penetrated by the ejaculatory ducts, which is largely occupied by glandular structures and which is prone to great increase of size in age, to be designated by the term "median portion"

The prostatic urethra commencing at the neck of the bladder, continues through the prostate in the erect posture downwards and slightly forwards, the great masses of the organ lie on either side of the canal There has been considerable difference of opinion as to which of the two commissures uniting these lateral masses was the larger or thicker of the two Most observers believe that in the normal condition the larger portion is found behind the urethra Mercier, on the other hand, asserted that the anterior stratum is larger and thicker than the posterior Thompson found, on examination of ten healthy adult prostates, the anterior and posterior commissures to be of about equal thickness in 7, posterior commissure thickest in 2, and the anterior in 1 The vesical boundary of the prostatic urethra is the uvula vesicæ, seen as a slightly rounded prominence of the floor of the neck of the bladder From this point forward the canal gradually expands a little and presents a general indication of hollowing or depression of the floor, varied by a central longitudinal elevation, the veru montanum This eminence commences in a faint whitish line directly in front of the uvula, and gradually rising for 6 or 8 lines, reaches its highest point (about ⅛ inch) in the central line of the urethra It widens and becomes rounded at the highest point, and then somewhat suddenly diminishing in size as it advances forward, exhibits on the anterior slope a small opening, then gradually lessening leaves the prostatic and enters the membranous urethra The depression of the prostatic urethra (*sinus prostaticus*) is then divided into two lateral furrows, one on each side of the veru montanum In these furrows may be observed numerous little orifices twenty to thirty in number, the mouths of the prostatic ducts They are found chiefly on each side of the eminence of the veru montanum, but a few may be seen both before and behind it The length of the prostatic urethra varies from 1⅛ to 1¼ inches Its diameter is usually represented by a fixed measurement, but as the surfaces lie in apposition, except when distended by a functional act, it is difficult to represent accurately the calibre The walls and surrounding structures are extensible and the calibre of the canal is consequently variable, corresponding within certain limits to the amount of pressure exerted Without unduly extending them, the diameter opposite the crest of the veru montanum may be placed at $\frac{5}{16}$ to ⅜ inch, but at each extremity of the prostatic limit the diameter is rather less

The whole of the urethra thus examined presents a surface of mucous membrane which is covered with cylindrical epithelium arranged in two layers, a superficial and a deep layer The membrane has, when fresh, a pale pinkish yellow tint, the structures which underlie it being pale unstriped and muscular, connective and elastic tissues, with fewer minute blood-vessels than are found in the membranous and bulbous portions of the urethra, where a redder tinge consequently exists These sub mucous structures are composed chiefly of the pale unstriped muscular fibres, intermixed with a small proportion only of the white fibrous and elastic tissues The muscular fibres are arranged in the longitudinal axis of the urethra and form a thin but somewhat dense and strong layer immediately beneath the mucous membrane throughout the prostate They continue to have a similar relation throughout the canal, although in smaller quantity than in this situation Posteriorly, they are continuous with the muscular layer immediately underlying the mucous membrane of the bladder It is by a development of these longitudinal muscular fibres of the urethra that the veru montanum is formed They divide to define the mouth of the utricle and admit the orifices of the prostatic ducts These cavities are lined with a delicate membrane and epithelium like that of the prostatic urethra itself

The precise mode of arrangement of the minute blood vessels beneath the prostatic mucous membrane is as follows From the neck of the bladder to the most elevated portion of the veru montanum very few of them are to be seen, and the mucous membrane is of a yellowish tint from their paucity in this situation In front of it, however, numerous fine vessels course forwards, side by side, for the most part in the axis of the urethra, but with a slight oblique divergence outwards, right and left of the pale line of the veru montanum prolonged into the membranous portion The mucous membrane is therefore redder in tint anterior to the eminence, and on examining it with a magnifying glass it is seen to be due to the minute and longitudinally branching vessels just described

The utricle or vesicula prostatica just described, is a small sac already referred to as opening on the anterior aspect of the veru montanum It is somewhat oval in form, measuring ordinarily from 2½ to 4 lines in length and from 2 to 3 lines at its greatest breadth, although occasionally found both larger and smaller Its posterior extremity is the widest and the anterior is the narrowest portion It is obliquely placed, the long diameter being directed towards or a little below the median portion and in the course of the ejaculatory ducts, which lie contained in the substance of its lateral walls The external orifice or mouth of the utricle is sometimes extremely small, and it has been seen occasionally altogether wanting The orifices of the two ejaculatory ducts were then found opening on the anterior of the veru montanum The sac of the utricle is made up of mucous membrane covered with cylindrical epithelium and of a sub-mucous tissue attaching it to some bands of white fibrous and pale muscular fibre, by which it insensibly unites with the mass of structures

around It contains mucous follicles which appear sometimes to secrete a dark reddish brown and jelly like material, at least such is found sometimes, nearly filling the sac When in a quiescent state the sides of the prostate urethra are pretty closely applied to each other and the mucous membrane then lies in very small delicate longitudinal plaits, with a very shallow groove between each A transverse section shows the canal to have a form generally approximating triangular, the apex being upwards The common duct formed by the junction of the vas deferens and of a duct of the vesicula seminalis enters, in close proximity with its fellow of the opposite side, at the base of the prostate, about three or four lines below the opening which transmits the urethra There is a well marked depression, in form pyramidal, with the apex directed inwards, in the base of the organ, which corresponds with the apex of the notch separating the two lateral lobes This depression penetrates the substance of the posterior or median portion, about three quarters of the mass lying between the ducts and the urethra, the remaining one fourth forming a thin layer between the ducts and the under surface of the prostate This proportion varies in different subjects, in all, however, the greater part of the mass lies between the ducts and the urethra A thin stratum of tissue one-fifteenth to one twentieth of an inch in thickness separates the two ducts as they perforate the organ side by side They then pass directly to the utricle and continue their course embedded in the walls of that cavity, one on each side, their little slit like orifices opening on the anterior part of the veru montanum, at the mouth of the utricle itself

The ejaculatory duct, from its place of entry at the base of the prostate to the orifice at the utricle, is about six lines in length It is composed of a mucous lining or an inner coat, some pale muscular fibres surrounding it, with connective tissue intervening The muscular fibres are arranged longitudinally in the axis of the duct, and are continued in those which underlie the urethral mucous membrane close to the mouth of the utricle It will be seen from the foregoing description that the pale or unstriped muscular fibre enters largely into the composition of the prostate This was first declared by Dr Handfield Jones, in 1847 In 1848 Kolliker, of Wurzburg, declared that the larger portion of the organ was constituted by the pale muscular tissue, and that the smaller portion only consisted of glandular tissue Subsequently Prof Ellis, of University College, London, Eng , closely investigated the same subject, and came to a similar conclusion

The tissues constituting the prostate passing from the urethra outwards consist, *first*, of the mucous membrane of the urethra, *second*, of a delicate layer of longitudinally disposed pale, or unstriped muscular fibres, mingled with a good deal of connective tissue and some elastic fibres, this layer forming part of a system of longitudinal fibres underlying and surrounding in greater or less quantity the whole urethral canal, *third*, a circularly disposed layer of pale or unstriped muscular fibres of considerable thickness posteriorly, where they become continuous with the circular fibres of the bladder and becoming thinner as they approach the membranous portion, over which they proceed and then terminate This layer contains also connective and elastic fibres like the preceding, *fourth*, beyond this lies the greater part of the glandular structure, properly so called, which intermingles with and is supported by a considerable portion of tissue composed in part of pale muscular fibre and in part of connective and fibrous tissues, which, interlacing with each other, constitute the rest of the organ It is this composite structure which, disposed in masses chiefly in the lateral direction on either side, gives form and character to the organ, *fifth*, the enveloping fibrous capsule just beneath this capsule, or the exterior of the proper stroma of the prostate, is a layer which consists of unstriped muscular tissue, attached to the inner surface of the capsule, and also continuous posteriorly with the external muscular layer of the bladder

The middle layer of unstriped muscular fibre forms a dense interlacing stratum in the meshes of which is found the glandular tissue The latter consists of tubular alveoli opening into elongated excretory ducts lined with columnar epithelium The alveoli are connected together by connective tissue associated with fibrous prolongations from the capsule of the gland, and with muscular tissue, the interglandular connective and muscular tissue being richly supplied with blood vessels and nerves, the arterial supply coming from the internal pudic, the inferior vesical and the hæmorrhoidal Its veins form a plexus, the prostatic, around the gland lying between the proper capsule and the sheath of the gland derived from the recto vesical fascia, and continous anteriorly with the posterior layer of the triangular ligament, and receiving in front the dorsal vein of the penis and ending behind in the internal iliac vein

The nerves of the prostate are the prostatic plexus of the sympathetic, which is derived from the inferior hypogastric or pelvic plexus, the latter plexus being made up by a union of branches from the hypogastric plexus, from the 2d, 3d and 4th, sacral nerves, and a few filaments from the sacral ganglia of the sympathetic It is well known that in certain affections of the bladder, rectum, prostate, etc , pain is felt along the perineum, in the penis, over the buttock, and down the thigh These parts are supplied by the pudic and small sciatic nerves, and the reason for the pain is explained by noticing that the very spinal nerves that join the plexus for the viscera, give off also, the pudic and small sciatic nerves, the former from the third and fourth sacral, the latter from the second and third Thus, the pelvic viscera and the skin of the buttock perineum and external genitals are all kept in association by the same spinal nerves The pain at the end of the penis felt in prostatic affections, and in stone or other maladies involving the bladder neck, is probably explained by the fact that the prostatic nerve plexus, (that supplies both the gland and the neck of the bladder) is continued to the end of the penis as the cavernous plexus It terminates at the very spot where the penile pain is mostly complained of viz at the posterior part of the glans

The ligamentous and muscular attachments of the prostate, the latter of which contribute in some measure to its mobility, consist first of the pubo-prostatic or anterior true ligaments of the bladder, and formed by the anterior border of the recto-vesical portion of the pelvic fascia, which passes from the posterior aspect of each pubic bone at its lower border, as a strong whitish band to the anterior surface of the prostate on its way to the bladder, where it becomes continuous with the fibrous structures which surround the neck of that viscus and belong to its muscular apparatus The muscular attachments of the prostate are the levatores prostatæ Each muscle of this pair arises from an oblique line on the posterior surface of the pubic bone, its most anterior fibres descending to meet those of its fellow just in front of and below the apex of the prostate, its middle and posterior fibres continuing to be inserted along the lateral borders In this manner the organ is, in a measure, suspended in its place

From the foregoing description we see that the prostate gland is not in the sense in which we describe the kidney, or the liver, or the heart, an organ composed of structures separable from and independent of the surrounding tissues, but as we have seen all its tissues except the glandular, form a part of and are continous with adjoining structures We notice too, that according to the most careful and reliable observers, such as Kolliker, Ellis, and others, that the glandular element constitutes one-third or less than one-third of the whole organ, so that it is more correct, anatomically to speak of it as a muscle We must also bear in mind that the glandular element is found chiefly in the posterior part of the two lateral lobes, and in the posterior commissure, none in the anterior commissure

Pathology —The most common as well as the most important, morbid states to which the prostate is subject, either consist in, or are associated with deviations from the natural size and form, as well as from the natural disposition of the structures entering into its composition Enlargement of the prostate commonly called hypertrophy, is an affection of a certain proportion of men after passing the prime of life, or to speak more definitely, the 55th year It is not an hypertrophy, inasmuch, as it is not, as a rule, a symmetrical growth of all its parts and tissues, but the enlargement affects sometimes one, sometimes both lateral lobes, sometimes the median portion alone, sometimes one lobe and the median portion, and sometimes the anterior or the posterior or both commissures Thompson found, as a result of the examinations of 123 enlarged prostates—found in four of the principal museums of London, including that of the Royal College of Surgeons—that in 74 cases, both lateral and the median portion were pretty equally enlarged In 19 cases, both lateral and median portions enlarged, but the latter in greater proportion than the former In 8 cases, general enlargement, but the right lobe predominating and very decidely larger than the left In 11 cases, general enlargement, but the left lobe predominating In 5 cases, lateral lobes only enlarged In 3 cases, the anterior commissure only or chiefly enlarged, and in 3 cases the lateral lobes and anterior commissure only enlarged, median portion being normal

The results of Dr Messer's examinations practically agree with Sir Henry Thompson's, and both observers found from the examinations of the prostates of 164 men at and above 60 years of age, that senile enlargement of the prostate, so far from being a change, invariably or even usually present in elderly men, is an exceptional condition, this condition affecting to a greater or less extent about one in three individuals, and that in about one in seven or eight the senile change was sufficient to produce appreciable symptoms during life

The character of the enlargement is not such as follows an inflammatory action, nor is it caused by any of the results of inflammation corresponding with those produced by the action of inflammation in other organs, but is a slow and gradual process due to an increased formation of tissues naturally present in the prostate itself or analogous thereto The enlargement may be due to a proportionate increase in both the stromal and the glandular elements, constituting, if the whole organ is affected a true hypertrophy, or the stromal constituents may be developed largely in excess of the glandular constituting stromal hyperplasia, or we may have an excessive glandular development constituting glandular hyperplasia, or we may have a rearrangement of the normal structures of the prostrate, fibrous and glandular in the form of tumors

The etiology of senile enlargement of the prostate has been a subject for theorizing and speculation since the days of John Hunter, who, while he said nothing directly as to its cause stated that he had seen anti-scrofulous remedies used in several cases Sir E Home, attributed it to the slow return of blood from the neck of the bladder, or in other words to passive congestion Sir Charles Bell considered it to be caused by any source of irritation which produced frequent contractions of the organ Astley Cooper believed it to be a normal senile change such as the arcus senilis or the ossification or calcification of the arterial coats Sexual excesses and celibacy have both been charged with being the causal factor Desault, Amussat, Civiale and Mercier, all discuss the subject but do not agree as to the cause The theory of Thompson is that the prostate being homologous to the uterus histologically, possesses the same inherent tendency to generate and develop fresh elements identical in character with those proper to the structure of the organs This tendency only existing during a certain limited period of life, say in general terms between 35 and 50 in the female and between 50 and 70 in the male, in the one case appearing in the form of uterine hypertrophy or tumor, in the other in that of prostatic hypertrophy or tumor These phenomena in the female are observed perhaps with greater frequency in the virgin than in the impregnated female, showing that they do not depend upon any force called into play by pregnancy, but are possibly inherent in the structure of the organ This theory

of Thompson's would certainly seem more plausible than the others and may I think be adopted in the absence of a better one With regard to the rapidity of senile enlargement, Thompson believes that may be influenced by those conditions that many eminent observers believe to be the cause of the enlargement itself, viz all forms of irritation and congestion In other words, the vital process of growth and tissue development are quickened and favored by whatever favors an increased supply of blood to the organ

One of the most important results of the anatomical changes that take place in the prostatic urethra and the neck of the bladder, as the result of enlarged prostate, is the interference with the normal flow of urine from the bladder Now, the amount of obstruction is not in direct proportion to the enlarged condition of the prostate, but rather depends upon the character of the enlargement Obviously, one of the first effects of an enlargement that is symmetrical or nearly such, is a lengthening of the prostatic urethra, but this alone need not cause the obstruction If the increased tissue is confined entirely to the lateral lobes or if in addition the median portion be but slightly increased the posterior urethra becomes lengthened, narrowed from side to side, but increased in its vertical diameter, so that no obstruction, or but slight interference with the outflow of urine results Again, if the enlargement is confined to one lateral lobe the prostatic urethra become elongated and curved with the convexity of the curve towards the normal lobe When we have enlargement of the median portions of the prostate, obstruction is likely to follow but not necessarily The growth may be centric or it may be eccentric or peripheral In the latter case we may have no obstruction while a very moderate degree of central enlargement of the median portion may present an obstacle to the urinary outflow of the most serious nature, so that one cannot decide absolutely by a tactile rectal examination, as to the extent or character of the prostatic barrier In some cases we may find on rectal examination a growth of the median portion presenting to the finger a very large and firm tumor, and yet in passing the sound the beak enters the bladder with only a very moderate depression of the handle showing the enlargement to be of eccentric character Of course the converse of this proposition holds true With a scarcely perceptible encroachment upon the rectal calibre, we find when the sound enters the prostate it comes to a sudden halt, and will only advance when the point is turned vertically, or nearly vertically upwards

From what has been said relative to the effect upon the outflow of urine, of the different forms of prostatic enlargement, we can with little difficulty foresee that the symptoms will depend upon the part of the prostate affected The rapidity of the increase of the abnormal tissue and the presence or freedom from exciting causes, such as exposure to cold, indulgence in wine or malt liquors, etc The first symptoms are a diminution in the degree of force with which the urine is expelled, next a hesitation in the appearance of the stream after voluntary effort, then frequency of micturition due to overflow from retention, feeling of weight, fulness and uneasiness about the hypogastrium, rectum and perineum, and these symptoms, unless obviated by the judicious use of the catheter and a proper attention given to the condition of the bowels, the diet, and the avoidance of excesses of all kinds, with a view to prevent all congestions and irritations of the affected tissues, gradually lead to complete urinary retention and bring us face to face with the question of palliative versus operative measures

If we stop a moment to consider the vast number of factors that may contribute to bring about an inability to empty the bladder, and the ever-varying degree in which each one of them may preponderate, we must, I think, admit that no hard and fast line of treatment can be recommended to overcome urinary obstruction associated and more or less dependent upon prostatic enlargement No one would think of proposing an operation until palliative measures had been exhausted, until the degree of atony of the bladder, if present at all, had been determined, and further, the enlargement ascertained to be of the median portion, and of such shape and relation to surrounding parts that it can be isolated, and when isolated and removed offers a reasonable prospect of relieving the obstruction Mercier, who operated 300 times previous to 1856, for prostatic obstructions, and obstructions caused by a bar of mucous membrane, or mucous membrane and sub-mucous muscular tissue at the neck of the bladder, was of the opinion that it was a safer operation to crush the obstructing part than to excise it

In more recent times, during the early part of the last decade, Professor Bottini has adopted the method of removing the prostatic obstructions by means of a wire heated by the electric current Professor Guyon, of Paris, who examined three patients of Mercier some considerable time after the operation, was not pleased with the result, and adds, when we examine the pathological specimens which the autopsies of prostatic patients have furnished, it is rare indeed to meet with an organ so formed as to afford the slightest hope that by any proceeding of incision or excision an iota of benefit could have accrued to the case Landerer, of Leipzig, reports, in the *Deutsche Zeitschrift fur Chirurgie*, that in doing the median operation for stone, he accidentally crushed off two pieces of the middle lobe, he then removed the whole of the projecting body The wound was healed in 14 days and the patient could urinate with a full stream This favorable condition has now lasted 1½ years, so that he does not hesitate to recommend the operation of crushing of the middle lobe through the median perineal incision In America, the operation of removing a part of the middle lobe by excision has been done by Belfield, of Chicago, and by others, but as to the present condition of the patients I am ignorant.

As this paper has already reached an undue length, I will close here, leaving what I have to say as to other forms of prostatic disease, together with clinical memoranda, for further consideration

THE GRADUAL PREPARATORY TREATMENT OF THE COMPLICATIONS OF URINARY AND FECAL FISTULÆ IN WOMEN,

Including a Special Consideration of the Treatment of Pyelitis by a New Method, and the Prevention of the Evils of Incontinence of Urine by a New System of Drainage

Abstract of a paper read before the Section in Gynecology of the Ninth International Medical Congress

BY NATHAN BOZEMAN, M D,

NEW YORK SURGEON TO THE WOMAN'S HOSPITAL OF THE STATE OF NEW YORK

In the course of my experience in the treatment of urinary and fecal fistulæ, as I encountered new difficulties, I have described from time to time the cases and the means by which I endeavored to overcome them, but all, especially the more recent of my results have not been published The object of the paper, of which this is an abstract, is therefore, to set these latter before the profession, and to combine them with what I have already written In this way, I hope to communicate, in a more systematic manner the results of my experience and observations, in this department of the subject of fistula, which have extended over a period of 34 years The object of my method of treatment, preparatory to the performance of the operation for the closure of a fistulous opening, is to prevent and overcome the injurious effects of incontinence of urine, and to remedy the complicating injuries and diseases of all the organs involved In other words, to remove as far as possible the obstacles in the way of the easy performance and success of the final operation, and to cause the diseased tissues to return to a state of health, so that, not only will the incontinence of urine be cured, but the functions of all the organs be preserved

Treatment and Prevention of the Effects of Incontinence of Urine—Inflammation and ulceration of the vagina, vulva and buttocks, due to the contact of ammonical urine, may be treated in the usual way, by cleanliness and by stimulating and astringent applications Although by these measures, the sufferings of the patient are relieved to a considerable extent, when for any cause, the closure of the fistula is long delayed, it is of the utmost importance that we should possess some form of instrument by which the urine may be drained away, and its contact with the mucous membranes, integument and linen of the patient be avoided

After many experiments, I have recently devised an instrument which accomplishes these results in a satisfactory manner, and have also been able to combine, in the same instrument, drainage with the dilatation of cicatricial contractions of the vagina The forms of the instrument, which concern us here, are intended to secure drainage alone, and I have called them utero-vesical and utero-vesico urethral drainage supports The former is applicable to most cases, to all positions of the body and is the most convenient The latter is suited to the recumbent position and to cases where the perineum is lacerated These instruments can be introduced and removed by the patient, whenever necessary and without difficulty They are self-retaining, small, simple, free from angles and sharp borders, are readily kept clean, excite no discomfort or irritation of the vagina, and do not press upon the rectum or bladder, nor interfere with locomotion

While possessing all these qualities in a high degree, they collect the urine, and conduct it away with a degree of perfection that, to the patient, is a constant source of wonder and delight I have now five cases in which the different forms of the instrument are in use In one of these cases, there is entire destruction of the urethra In all, the instrument functions perfectly

The Treatment of the Complications of Urinary and Fecal Fistulæ—Very few cases of fistula are simple The same cause, the pressure of the child's head, which produced the perforation of the vesical or rectal wall, injures to a greater or less extent other parts of the vagina and frequently the uterus, ureters and urethra These injuries and the distortions of the structures involved, the result of the contractions of the cicatricial material produced in the healing process, constitute the most frequent complications In the worst cases, to them are added subsequent disease of these organs and the bladder, and fixation of the uterus, the consequence of puerperal cellulitis and peritonitis

Cicatricial Contractions and Distortions of the Vagina—General thickening and rigidity of the vaginal walls and narrowing of the vagina by the presence of cicatricial bands and adhesions, render the exposure of the fistula difficult, and tend to prevent the easy approximation of its borders The operation for closing the opening is thus made difficult, and owing to great tension, the sutures cut, and it fails

The means by which I overcome these difficulties, are mainly, division of the cicatricial material and gradual dilatation of the vagina In cases in which the vagina is very much contracted my method consists, first in the section of all the prominent bands and adhesions, and afterwards in the dilatation of the vagina with hard and soft instruments

When it is neccessary to give ether, the patient is placed in the knee chest position and secured by means of an apparatus which I have had constructed for the purpose In the ordinary treatment of the case, this is unnecessary, I place the patient simply in the supported knee elbow position The parts are exposed to view by means of my dilating speculum, and perineal elevator, and the bands, which are at the same time rendered tense and prominent by these instruments, are divided while on the stretch by means of sharp and probe pointed bistouries, and the peculiar knife which I show you

The subsequent dilatation of the contractions of the vagina is produced by hard and soft dilators On account of differences in form and in the manner in which they are used, I have divided them into two classes, the vulvovaginal and intravaginal

The hard dilators, which I show you, are made to combine drainage with dilatation The vulvovaginal can be distinguished from the intravaginal by their greater length, and the beak-like extremity which

rests on the perinæum The intravaginal instruments are worn altogether inside of the vulva, and rest upon the posterior surface of the arch of the pubes and perinæum A set of the vulvovaginal dilators consists of five sizes, ranging from 30 to 50 millimeters in diameter, and a set of the intravaginal of eight sizes ranging between 30 and 65 millimeters

The soft dilators are made of coarse sponge covered with oil silk, and may be of any size up to 70 millimeters in diameter or larger if necessary The difference between the vulvovaginal and the intravaginal forms of these soft instruments is that the former are made longer but never so large, the sizes being graded like the hard instruments I have been unable to combine drainage with dilatation, when the sponge instruments are used, but if they are frequently removed and the urine which they absorb, squeezed out, the vagina and vulva may be kept comparatively dry Althought only a very imperfect sort of drainage, which I have called sponge absorption, can be obtained with sponge dilators, they are superior in many respects to the hard instruments A much larger dilator can be introduced and being soft, it causes less pain In virtue of its elasticity, the sponge accommodates itself to the shape of the vagina, when the organ is irregularly contracted and by the imbibition of urine, increases in size after introduction

Time, patience and perseverance are all that are necessary to produce by the gradual division of opposing cicatricial bands and the systematic use of larger and larger dilating instruments, a distension of the vagina nearly equal to that caused by the child's head, at the time of the injury As the dilatation proceeds, the exact nature of the lesions becomes more evident, and the form and relations of the fistula to the surrounding structures are more distinctly exposed to view, the cervix uteri which was perhaps altogether hidden, becomes visible, and the anterior and posterior culs de sac are restored, the vaginal walls are relaxed and the uterus made movable The mucous membrane of the vagina loses its fiery red hue and assumes a natural pink color, the inflammatory thickening of the vaginal walls melts away beneath the pressure, and the borders of the fistula lose their leather like hardness, become smooth and soft, and may be more easily approximated

Fixation of the Uterus —When there is great loss of tissue at the fistulous opening and the uterus is fixed, the remnants of the septum can never be sufficiently stretched to bridge the interval The uterus must be rendered movable so that the cervix can be drawn down, and made subservient to the closure of the opening

The fixation of the uterus may be overcome by upward pressure, made with the dilators already described and by a sort of passive motion of the uterus, which is secured by traction, frequently repeated, with a hook fastened in the cervix

The practical use of these measures is sufficient to demonstrate their efficiency, but, in order to render the results obtained by them clear to all, I made an experiment, while in Vienna, in 1875, on a case of fistula, in which there was immobility of the borders, due to fixation of the uterus, the results of this experiment have been reported by Bandl [1] At the beginning of the treatment, the edges of the opening could not be approximated by any amount of force After the section of the band and dilatation of the vagina had been continued for 4 days, they could be brought together imperfectly, by the exercise of 2,800 grams of traction, measured by a spring scale After the continuance of the treatment for 17 days longer, 120 grams were sufficient for this purpose, and the operation for the closure of the fistula had become easy

The advantages, secured by the use of these preparatory measures, are also well illustrated in certain more special forms of fistula By the aid of my button suture, and these preparatory measures, with the modifications which I have described fully in my paper, I have been able to treat successfully vesico uterovaginal fistulæ with incarceration of the cervix uteri in the bladder, restoring the cervix to its natural position in the vagina and closing the vesical opening without the formation of a pouch in the bladder, I have been able to reach and to close vesico uterocervical fistulæ, attended with loss of tissue, even when the opening was situated entirely above the vaginal junction, and have met with the same success with recto utero vaginal fistulæ, with incarceration of the cervix in the rectum All these conditions have been, and are still, considered without remedy, except by kolpokleisis, occlusion of the os uteri, or by the perpetuation of the incarceration of the cervix in the bladder or rectum

Cystitis, Contraction and Prolapse of the Bladder are frequent complications and must be treated

The principal cause of *cystitis* is the retention in the bladder of stagnant pools of urine in pouches of the mucous membrane, or as the result of imperfect drainage of the urine through the fistulous opening The saculation of the vesical mucous membrane at the base of the bladder, is due to the distortion of the anterior wall of the vagina by cicatricial bands

The treatment of cystitis consists, therefore, in the frequent irrigation of the interior of the bladder, and the obliteration of the folds of the mucous membrane by dilatation of the vagina

Atrophy or *contraction* of the bladder is best treated by obturation of the fistulous opening, by means of an oiled silk sponge dilator placed in the vagina A sufficient quantity of urine is thus retained in the bladder to gradually distend its walls

A *prolapsed bladder* should be reduced in the supported knee chest position, the abrasions of the mucous membrane touched with nitrate of silver, and the reproduction of the condition prevented, by filling the vagina with one of the forms of dilators already described

Injuries of the Ureters —One of the ureters may be opened by a slough, which does not penetrate the whole, thickness of the septum By an injury of this kind, a uretero vaginal fistula is formed One or both of the ureters may also form, a part of the border of a vesico-vaginal fistula In the first form

[1] Wiener Medizinische Wochenschrift Nos 49-52 1875

of injury, the ureter must be turned into the bladder before the fistula is closed, thus converting it into a vesico uretero-vaginal fistula In all cases, when the ureters are involved, unless they are slit up on their vesical surfaces, the orifices are liable to be obstructed by the sutures or be occluded by the apposition of the borders of the fistula This little operation is best done, as a preparatory measure, long enough before closure of the fistula to allow healing to occur Stenosis and eversion of the orifices of the ureters frequently occur in these cases, and it is therefore important to ascertain before closing a fistulous opening, whether these conditions exist When such a condition is present, the lower part of the ureter should be divided, and the incision should extend through the vesical mucous membrane, and be followed by dilatation with sounds, if necessary

Pyelitis —The causes, which lead to the development of pyelitis as a complication of fistula are, cystitis and obstruction of the ureter The principal symptoms, which I have observed to be present in this disease, are more or less constant pain in the lumbar region, attacks of renal colic, nausea and vomiting, anæmia, emaciation and the cachexia of chronic suppuration At times, the course of the disease is varied, by the occurrence of severe rigors, accompanied and followed by great pyrexia Pus and blood may be seen to exude from the orifice of the ureter which is exposed to view by the fistulous opening

I have recently devised a new method of treatment for this disease, and have used it in two cases, both of which are now cured It consists essentially, in dilating the ureter and washing out the pelvis of the kidney by means of a catheter

In my first case, which I have reported at length in my paper, the pyelitis involved the pelvis of the left kidney, and occurred as a complication of the large urethro vesico-utero vaginal fistula, implicating both ureters and the greater part of the septum It probably was occasioned by the obstruction of the orifice of the ureter, due to the contraction of the cicatricial border of the fistula, of which it formed a part

The patient was suffering, from frequent paroxysms of renal colic, rigors were occurring at short intervals, and her temperature was constantly elevated, ranging between 102° and 105° Pus could be seen exuding in considerable quantities from the left ureter The patient was emaciated and her complexion was pale and sallow She was evidently rapidly dying from exhaustion, induced by the fever and the pain

The condition of the patient continued to grow worse, and the case more hopeless, until December 26, of last year, when I passed a small olive-tipped catheter through the ureter into the pelvis of the kidney Carbolized water was then injected with a syringe, and a small quantity of fœtid pus washed out The catheter was allowed to remain in place 24 hours without causing any evil consequences, and the irrigation of the pelvis of the kidney repeated, at frequent intervals Afterwards the douching was repeated daily, the catheter being introduced and removed without difficulty

The condition of the patient improved after this treatment was begun with remarkable rapidity, the temperature became normal in 24 hours, the pus gradually diminished in quantity, and, at the end of six weeks entirely disappeared The patient has since gained about thirty pounds in weight, her general health has become good, and the fistulous opening is now ready for operation

In the course of the treatment of this case, I made several interesting observations on the relative secreting capacities of the two kidneys, the details of which I have not time to tell you in this abstract I also caused to be constructed the flexible steel renal sound which I show you It is intended for purposes of diagnosis rather than of treatment, but was of service in this case, in dislodging the detritus from the pelvis of the kidney

Encouraged by my success in this case, I conceived the idea of extending this method of treatment, to cases of pyelitis when no fistulous opening existed Fortunately, I soon had an opportunity Mrs B came under my care She gave a history of symptoms similar to those already described Hæmaturia formed a marked feature of the case, and had continued for 2½ years The pelvis of the right kidney was suspected from the location of the pain to be the seat of the disease In order to expose the right ureter, an opening was made in the bladder at a point where it pierces the vesical mucous membrane

The name which I suggest for this new operation is kolpo-uretero-cystotomy, it is appropriate because it corresponds with the established nomenclature, and serves to distinguish the operation from kolpo-cystotomy done for cystitis, and kolpo-ureterotomy, which may be done in future

When the orifice of the ureter was thus exposed, blood was seen exuding from it The ureter having been made accessible, the subsequent treatment was the same as in the previous case, and the result equally fortunate The discharge disappeared in a few weeks The use of my utero-vesical drainage support prevented all inconvenience from incontinence of urine, and made the patient so comfortable, that haste in closing the opening was considered unnecessary She was therefore sent home to Charleston, and instructed to return for this purpose, when she was stronger and fully restored to health

She wrote me on August 12, the following account of her condition "The drainage works perfectly There is no escape of urine, except sometimes a little while lying down I do not suffer from any irritation whatever The instrument keeps the uterus in position I have not suffered any pain in the kidneys I feel better than I have for years I have just weighed, so will acquaint you with the numbers—109 pounds, having gained 19 pounds in 3 months, (that is, since the operation) I am able to attend church services I can either ride or walk Neither gives me any uneasiness My friends look at me, and speak of my improvement with astonishment"

All the complications of gravity of urinary and fæcal fistulæ having now been studied, what I have

already said, may be, in conclusion, enforced by a brief summary of certain important facts and principles, and an enumeration of the results that I believe may be secured, by the employment of the methods of treatment which I have described

1 The importance of the complications of fistula has not been duly appreciated They form in many cases the principal difficulty in the way of the successful performance of the operation, for the closure of the fistulous opening In other cases, when the fistula is cured, but the complications left without treatment, they lead sooner or later to suffering or to the death of the patient The greatest care should, therefore, be taken to discover and remove them

2 Kolpokleisis, occlusion of the os uteri, and incarceration of the cervix in the bladder or rectum, are unjustifiable operations They destroy the functions of the genital organs, and lead to cystitis, the formation of renal and vesical calculi, pyelitis, and other grave diseases Moreover, they are unnecessary operations By means of the gradual preparatory treatment of the complication, and, by the aid of my button suture, and dilating speculum, I have been able to overcome all the difficulties which have been described as indications for their performance

3 The association of intra-vaginal drainage with dilatation of the vagina, is a great improvement The inconvenience and evil effects of incontinence of urine are thereby lessened, and the duration of the treatment is shortened, by the more rapid healing of the incisions, and the formation of less cicatricial material in the reparative process

4 We now possess a means of palliating the suffering due to incontinence of urine, in the small percentage of cases of fistula which are incurable by any method—even the dangerous one of kolpokleisis I believe some form of drainage instrument may be adapted to every case, and these patients may be thus restored to the enjoyment of life, and the performance of its duties

5 The possession of a system of drainage will widen the scope of the operations of kolpocystonomy done for cystitis, by removing the evils of incontinence of urine, now the chief objection to its performance

6 Finally, I believe the operation, which I have called kolpo uretero cystotomy, followed by the exploration and treatment of the diseases of the ureter and pelvis of the kidney, has a brilliant future of usefulness before it In the treatment of pyelitis, renal calculi and obstruction of the ureters, it will restrict within narrow limits, the operations of nephrotomy and nephrectomy

---

PRACTICAL REMARKS ON THE CAUSES AND TREATMENT OF ENTERO-COLITIS IN INFANTS

Read in Section on Diseases of Children, at the Thirty Eighth Annual Meeting of the American Medical Association

BY S B SPERRY M D ,
OF DELAFIELD WIS

Believing as I do that much of this disease is due to ignorance and negligence on the part of nurse or mother, and that the physician is largely to blame for the same, I purpose in these remarks to refer to some of the common mistakes of nurses that have come under my observation, and to speak of the correction of the same The fatality of this disease, and its importance, the possibility of doing so much towards its prevention, are reasons enough for this paper being read I think it is within the bounds of truth to say that two thirds of the cases could be prevented if we had the power of making mothers do what is right, and of overcoming their ridiculous prejudices

It is more evident that this subject of the causes should be considered when the failures are due to small things which only too many physicians consider insignificant and beneath their notice The principal cause of entero colitis is undoubtedly improper food, *plus* certain causes over which we have no great control Indeed, I have never seen a case in an infant properly fed Teething, heat, age, play their part, but are not properly causes Is not the history of almost every case about this "Why Doctor, the baby has always been so well—we never have had any trouble with it—it has gone to the table with us, and eaten *just what we did* The baby had diarrhœa a few weeks ago, but has been getting better off and on until a few days ago it got very bad" This is the usual story *Eaten just what we did* is the key to the whole story Not satisfied with its doing well they must urge it on and take it to the table because it *seems* so hungry or some kind neighbor thinks the baby too poor or that it ought to have something to eat to strengthen it It is perfectly astonishing to find how few mothers give a thought as to how an infant should be fed They may be careful about its clothing, about its bath, about the temperature of the room, but know absolutely nothing when they come to its food It is a man on a small scale, they reason, and it needs man's food on a small scale—and it usually gets it Ask one of these mothers how they feed the baby "Oh, I nurse it," which is just the best half of the story Unless we are very careful in questioning we will not find out what is most important to know, that she also feeds the infant

This is by no means so insignificant a thing that we can pass it over We fail just because we are not careful as to just such things as these Now this infant we speak of has breast-milk, and what else? potatoes in all human probability, or oatmeal or rice We all know that intestinal digestion is at its minimum in infants, and although some of the starch may be digested most of it acts as an irritant and passes off undigested By these repeated insults to intestinal digestion we finally have set up a catarrh, an entero-colitis, mild at first, but getting worse with periods of improvement, each relapse being worse and leaving the infant in a half starved condition I believe it is a common and great fault with physicians in neglecting to find out *exactly* what the infant has been fed on Improper food—too much—and food too often is what causes this disease, and that this is not gone into thoroughly is why the disease is not cured It is not usually for a lack of skill in applying drugs that physicians fail, but in dealing with the

food, an indifference or failure to understand the absolute importance of the question Mothers must be continually watched, questioned and instructed over and over again

What tries our skill and patience are hand-fed babies For it is hard to get the proper food and harder still to keep the mother to one kind The only hope is to have the full confidence of the nurse or nothing can be done I know of no better way than to instruct them fully as to infant digestion—the value of foods—why it should have this and why not that Mothers are continually saying "Why don't physician's publish books on this subject?" but even with the excellent works of Jacobi, Keating and others they need the verbal instructions, they want the physician to show interest in the case I also warn them against seductive advice of friends They must be taught that artificial food requires careful consideration and trial before we find just what the infant needs "Line upon line—precept upon precept," over and over again must they be instructed, and not until then will you have them safely and surely in your hands Young mothers must especially be warned against the woman who talk about what their mothers used to do It is much easier to get ahead of these women than correct their bad advice

The pathology of entero-colitis is simple, and all I wish to call attention to is, that the liver and stomach remain comparatively free from disease until the last The vomiting is probably caused by the inflammation around the ileo-cæcal valve In the last stage passive congestion of the different organs is likely to supervene, especially of the brain and lungs

The treatment may be considered under two heads dietetic and medicinal

The diet for infants should be but one thing, milk If it is an infant that is fed on breast milk then we are to emphasize the fact that nothing else should be given, no bread, no crackers, nothing farinaceous Sometimes, when the diarrhœa is very severe, it will do to stop the milk in part or wholly, substituting for it beef-tea and toast-coffee If it is hand-fed what shall it have! Last year I presented a paper before this Section on this subject, entitled "The Best Substitute for Mother's Milk" Another year's experience confirms me in this belief that it is a perfect substitute The mixture consisted of fresh cow's milk diluted with barley-water and sweetened with sugar of milk—it is simple and easily prepared, and it is very necessary that it should be properly prepared How shall we tell the nurse to prepare this food? First, only enough should be prepared for each time See that the milk is not sour, and know whether it is skimmed or unskimmed The nurse will be unable to tell whether it is sour unless she have some test paper, which you should provide for her If acid it should be corrected with bicarbonate of soda or lime-water Should lime-water be used do not carry the dilution too far The barley-water is prepared by adding a pint of boiling water to two table-spoonfuls of granulated pearl barley and after boiling for five minutes remove and strain

Now, the first you know the nurse will be adding no barley, or will not strain it, and boil too long I have also had them add *half a cup* of pearl-barley instead of a table-spoonful or two, with the idea that it would make the child grow It may be prepared as directed in Meigs' mixture, the milk sugar being added to the barley-water When it is to be used all that is necessary is to heat the prepared barley-water and add it to the milk The milk should not be boiled (as it has been shown that there is an indescribable, unmeasureable something lost) unless you wish medicinal effects from it Milk sugar should always be used, and the reason given the nurse for so doing

With this food you have a perfect substitute for mother's milk If then the infant is not getting proper food change its food to this mixture, and then correct the catarrhal condition and flatulency with soda, bromides and some mint During the very bad spells the diet must be entirely changed and the work taken from the irritated intestines, and thrown entirely upon the stomach by giving beef-tea and toast-coffee, ½ to 1 teaspoonful of beef-tea and toast coffee as it calls for it As the symptoms abate I return to the milk diet

As for the medicinal part of the treatment, I use bicarbonate of soda, bromide of potassium and tincture of hyoscyamus I correct the irritable and painful condition of the mucous membrane with mild counter-irritation, and then give $\frac{1}{20}$ or $\frac{1}{30}$ of a grain of aloes in a triturate every 3 hours, which acts as a tonic or by its substitutive action

But it is in the stage of collapse that I have seen some remarkable results by giving large doses of chloral After losing some cases of the disease when following well-known authorities, I came to the conclusion that something different must be done Very soon I had an opportunity to try an entirely new plan One night I was called out into the country to see a baby which was very sick with "summer complaint," and the messenger told me he did not think I would find the child alive I found the child (7 months old) half conscious, rolling its head from side to side, which it had done for the past 24 hours, eyes but half open, head hot, pulse weak, rapid and irregular, extremities cold It would drink half a dipper of water at a time, and it would go literally through it The child had been sick two or three weeks, and with the usual history I gave the child five (5) grains of chloral, which it kept down It was asleep in 5 minutes, and I had it placed in its cradle with bottles of hot water placed to its feet and body, and cold to its head I also had some beef tea made immediately, and toast-coffee, the beef-tea to be given every 3 hours, a teaspoonful, and the toast-coffee whenever it wanted drink Brandy was added to the toast-coffee The child was made to sleep for 24 hours with chloral, and the irritability of the digestive tract was overcome by bismuth and calomel, and quinine as a tonic

In two days it was decidedly better, and then the milk was gradually given it, with strict injunctions as to preparing it The child made a good and rapid recovery After this I had other cases like it and found chloral entirely satisfactory The object in giving full doses of chloral is to get the brain entirely insensible to reflex action These large doses may

seem risky, but small doses are not sufficient Even in pseudo hydrocephalus I do not think chloral is contra-indicated, as it relaxes the arterioles, thus bringing the blood to the surface

ABSTRACT OF A PAPER ON ANTISEPTICS IN MEDICINE AND SURGERY

Read before the Medical Society of the District of Columbia, May 4, 1887

BY M G ELLZEY, M D,

PROFESSOR OF CHEMISTRY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF GEORGETOWN, D C

It is no longer an hypothesis, but a scientific fact, clearly and unequivocally established, that certain bacteria are necessary factors in the causation of certain diseases One question remains only debatable Which are and which are not germ diseases? It may be debated whether the bacteria and their spores or their poisonous excreta be the actual *materies morbi*, but this is a question of secondary importance It is of the very utmost importance to the progress of scientific medicine and surgery that the entire life history of these low organisms should be fully known, to the end that the unscientific rubbish which obscures the subject may be brushed away, and the facts of essential importance brought within reach of the profession in a clear, compact and manageable form The first essential fact in the natural history of the group is that all these lowly forms belong to the lowest group of plants known to naturalists Some of them cannot live in the presence of free oxygen, others need a limited supply of that gas Organic matter, a limited supply of oxygen, water, and salts are the generally essential conditions for the reproduction, growth and development of disease-producing bacteria and micrococci Hence the dangerous character of damp, dark and dirty places, and hence the inestimable value of scrupulous cleanness, effectual drainage and free ventilation, with free and copious supplies of light for all places of abode, and above all for hospital wards and sick rooms These are nature's great antiseptics, more and greater than all bichlorides and carbolic sprays It is among the tissues of the higher organisms that the optimum of the life conditions of bacteria would be found, except for the domination of physiological energies over the whole area of their environment Before the organic matter of living tissue can furnish pabulum for bacteria the tissue must first die in whole or in part, and the power with which bacteria are endowed to surround themselves with *toxic* excreta brings them into formidable resemblance to beasts of prey, that kill first and then devour We see, then, how everything which tends to weaken the physiological forces of the organism, to lower the general vitality, prepares the way for a fatal assault by swarming multitudes of pathogenic bacteria

It is for the destruction of bacteria and their spores that we use antiseptics So long as we are dealing with refuse materials and substances outside the living body we may use disinfectants in any degree of concentration necessary to secure their efficiency, or, following the Mosaic decree, we may even burn such materials with fire But within the living body we are met by the limitation of the power of the organism to withstand the action of efficient germicides Man cannot withstand the toxic action of any known reliable germicide in germicidal strength Germicidal medicine, therefore, is beyond the possibilities of the present We cannot kill bacteria or micrococci, still less can we kill the spores, after they have gained access to the interior of the living body Our therapeutic measures must have reference to the possibility of rendering the fluids and tissues more or less unfavorable media for the development and nutrition of pathogenic bacteria, and of strengthening and fortifying the vital resistance of the tissues It is not possible to make of the fluids and tissues of a man's body a germicidal pickle until after the man is dead, and from the way some dissecting rooms smell, one would think not easily then

It is much to be regretted that our knowledge of the limits of the germicidal powers of the best of the known germicides is far from being exact The spores of these bacteria possess resisting powers against the action of the best germicides enormously greater than do the developed bacteria themselves No two bacteria and no two of the different spores possess the same resisting power against any particular germicide The medium in which the bacteria may have been developed, and the medium in which they are brought in contact with the germicide, influence their resisting power to a very important but as yet undetermined extent A particular medium may increase the resisting power of one and greatly diminish that of another of these bacteria Blood serum, being an alkaline fluid, nearly destroys the germicidal powers of iodine by converting it into iodide, whereas it tends rather to increase than to diminish those of mercuric chloride Yet the germs themselves will be more vigorous and harder to destroy in the living body than in pure chemical solutions, in which an arrest of their nutrition may bring the germicidal powers of starvation to the aid of the drug If, then, we have determined the degree of concentration of the solution of mercuric chloride necessary to destroy anthrax germs in chemical solutions outside the body, we are not in a position to determine the necessary strength to destroy the germs and spores of disease germs of other species within the abdominal or utero-vaginal cavities or in a superficial wound, or in any individual subject, seeing that we cannot calculate the factor of vital resistance Temperature is a potent factor in the life conditions of these organisms, as Pasteur has beautifully shown We do not know the optimum of temperature for septic germs With regard to some of the most formidable disease germs Pasteur demonstrated the optimum of temperature to be 100° F, whereas 106° F was fatal to their development within the fluids and tissues of living animals—facts which have some tendency to make us pause in our antipyretic enthusiasm

It is frequently stated in the journals that mercuric chloride is fatal to germs and spores in strength of 1 to 20,000 or less, whereas it is safe as an antiseptic

injection or irrigant in strength of 1 to 2,000 Neither of these statements is correct The best experimenters place the germicidal powers of mercuric chloride at from 1 to 5,000 to 1 to 6,000 for developed germs, 1 to 1,000 for spores after direct continuous exposure to full strength from ten minutes to half an hour, de la Croix found germs still to develop in meat juice at a bichloride strength of 1 to 8,000 Most of the results of this observer are confirmed by Koch Brunton concludes that the only reliable germicide to destroy these organisms by merely brushing over the infected articles is bichloride of mercury, that is, to destroy both germs and spores, and that a bichloride solution even as weak as 1 to 1,000 seems effectual after after a *few minutes'* exposure These statements contain the latest results of our latest observers, and the extravagant statements above alluded to cannot be derived from competent authority

As to carbolic acid, its germicidal powers are surprisingly low It is not reliably germicidal in media favorable to its action in less strength than 10 per cent Carbolized oil, once so much used, is scarcely germicidal in strength of 50 per cent Carbolized sprays are wholly worthless, and those merely scented solutions so much in vogue are equally useless Such sprays and solutions may indeed, and often do, produce toxic effects upon operators and patients, but are innocuous to germs and spores In view of known facts it ought to be clear to the humblest understanding that carbolic acid is useless as an antiseptic in sufficient concentration to make it a deadly poison to man The use of dilute solutions and sprays in surgical practice is not founded in any scientific justification It cannot prove destructive to germs or spores, and is of no other possible or conceivable use The use of carbolic acid should be confined to the disinfection of instruments, and for this purpose its strength should be rather more than 1 to 10 The solutions of 1 to 40 in common use are entirely inefficient and worthless The trifling quantities of carbolic acid added to all sorts of washes, ointments and prescriptions for internal and external use serve only to make the compounds disagreeable to use Increasing the volume of such solutions to any extent does not render them germicidal, but may cause dangerous toxic effects from their indiscriminate use No surgeon ought to suppose that he is rendering his instrument aseptic by dipping it momentarily in a 1 to 40 solution of carbolic acid The solution, he should know if he does not, should be 1 to 10, and the exposure to its action in no case less than ten minutes He must know that he cannot hope or expect to render an open abdominal cavity aseptic by the use of carbolic sprays or douching with faintly carbolized water, yet, if copiously applied, either the spray or solution may poison the patient fatally Whatever criticisms apply to the use of weak and inefficient solutions of carbolic acid for antiseptic purposes, apply with equal force to the use of mercuric chloride or other antiseptics If of less than germicidal strength there is no rational justification of their use, if of germicidal strength they are formidably dangerous We read constantly of the use of corrosive sublimate in solution of the strength of 1 to 2,000, or even 1 to 1,000, for the irrigation of large surgical wounds, or, for example, of the utero vaginal tract immediately after delivery It is not denied that toxic symptoms, and death with toxic symptoms, have followed such practice in the hands of very eminent practitioners Surely no eminence justifies a man in fatally poisoning his patients To one dead or the surviving friends it is all one whether death came from the hands of eminence or obscurity A solution of corrosive sublimate of the strength of gr ss–¼ f℥j cannot be safely employed to render aseptic any absorbing surface of considerable extent, a weaker solution, however copiously applied, while it may poison and kill the patient, cannot kill the spores nor prevent their development and reproduction as fast as the antiseptic is absorbed, flows away or is diluted and washed off by the secretion natural to the part Consider, also, the difficulty of applying a bichloride solution, for example, to every point in the entire utero-vaginal tract, plicated, creased, folded and obstructed with clots and secretions, as is the case shortly after delivery We could not be sure of reaching every point by injecting gallons of fluid If I could maintain, in the face of all obstacles, a solution of 1 to 1,000 mercuric chloride at the original strength in contact with every point of that vast mucous tract, I could render it certainly aseptic But what of the woman? Would she not be well nigh certainly poisoned? and would not criminal responsibility attach to me? It is within my power to know that my person and my instruments are aseptic or to make them so If I fail to do so and my patient dies as the result of my carelessness or ignorance, it is my fault

If I describe my own methods I shall be better understood I direct my efforts with scrupulous care to the disinfection of my instruments and person I boil my sponges in dilute muriatic acid and keep them for some hours in a 12 to 15 per cent solution of carbolic acid from which, just before using, I transfer them to boiling water which has been boiled for at least a half an hour My instruments lie covered in a similar solution for at least a half an hour, and at the moment of using them I transfer them to and pass them through boiling water I cleanse my hands and arms with Castile soap and aseptic water, and finish by rinsing them in a bichloride solution of 1 to 1,000 I wash the external parts about the seat of operation perfectly clean, and finish the sponging with the 1 to 1,000 bichloride solution

The operation done, I get the wound thoroughly clean with the aseptic sponges before closing it with aseptic sutures taken at the moment out of the carbolic solution and passed through the boiling water, again washing and cleansing the external parts perfectly, finishing by sponging with bichloride solution Lastly, I apply a pad of absorbent cotton covering the wound completely and making a complete septic screen, which I secure in place, if small, by court-plaster, if large, by bandages in addition, as may seem necessary I leave the primary dressing in place until I find some reason for removing it, often until the sutures are to be removed, and often then the

cotton is scarcely soiled or stained, and the wound healed by first intention If the carbolic and bichloride solutions are excepted the remaining method is the same I used as a military surgeon during the latter two thirds of the war and ever since I dressed all my wounds, surgical and others, with dry lint removed as infrequently as possible, and with infinite advantage over the cold water dressing then in vogue and all greasy and unctuous applications frequently renewed Now I know that I was using a perfect aseptic screen, for scientists and investigators use the cotton plug to secure the contents of their flasks and tubes from the access of atmospheric germs It prevents absolutely the access of germs to the aseptic preparations in the flasks and tubes, and it will and does keep them off the surface of wounds It is plain that every time an aseptic dressing is unnecessarily removed from an aseptic wound, it is a useless exposure to the danger of septic infection and an unnecessary disturbance of nature's reparative work

One thing more I deem of the utmost importance in the aseptic precautions necessary in surgical and obstetrical practice, is to limit the number of persons present to those positively necessary to render assistance No surgeon has a right to subject any person to operation in the presence of persons who may have come from questionable sanitary surroundings to the operating room, unless in cases of accident or emergency when the surroundings are not within his control As an *argumentum ad hominem* I put it interrogatively, has any surgeon a right to wear for merely ornamental purposes profuse locks of comely hair, or an immense shaggy, pendant beard? A man may, of course, carry this sort of precaution to whimsical and foolish extremes, but scarcely, if he is a man of sound scientific culture and natural good sense

I am not willing to close this paper without distinctly reaffirming my dissent from the opinion of those who hold that we may safely irrigate large absorbing surfaces with bichloride solutions of the strength of 1 to 2,000, or ¼ of a grain to the ounce It is, in my opinion, speaking as an experienced toxicologist, extremely hazardous to attempt to render the utero-vaginal tract after delivery aseptic by the use of so formidable a solution I have known deaths after such washings out with ominous symptoms, deaths which I firmly believe to have been caused by those washings out, and further, I believe there were no valid indications demanding or justifying resort to those washings-out Relying upon personal experience I believe that such proceedings are neither necessary nor useful if the lying in has been conducted in the light of modern science I have practiced medicine 27 years, and during a large part of that time have been extensively engaged in obstetric practice I have never washed out, and intend never to wash out the vagina of a recently delivered woman except with warm water for the removal of the débris of an embryotomy I have never left a woman from my first case to my last, inclusive, until every particle of soiled clothing was removed from the bed and person, the external genitals thoroughly cleansed and a clean napkin properly applied, and in the fact that I have never yet seen a case of septicæmia in my own practice I realize the justification of my practice

The best Listerian lecture I ever heard was delivered by the late Professor Charles D Meigs in 1859, when I was a student at the Jefferson Medical College It was on the conduct of a labor Preliminary to the lecture the janitor brought in a conspicuous array of soap, water, and clean towels Then followed the Professor, and he was received, as he always was, with hearty applause First bowing right and left in acknowledgment he pulled off his coat, removed his cuffs, rolled his shirt sleeves up and, soaping his hands and arms above the elbows, washed them, and then rinsed them in clean water, and finally dried them carefully and, taking a bottle of cologne, applied some of it freely to his hands Then turning to the class he said slowly "In the conduct of every labor the first essential thing demanded alike by safety and decency is to wash your hands Wash your hands first! Wash them clean! Wash them always, don't forget it How are you to tell, how am I to know that my servant who handles my reins hasn't got the gonorrhœa?" Many regarded all that as excessive mannerism and affectation It was the very best kind of teaching I have known and heard very many public teachers, some good, some bad, some indifferent, some very few great ones, the greatest of all was Professor Meigs That typical hand washing has been throughout my professional life a guiding star

---

SOME OF THE CAUSES OF NON-SUPPURATIVE DISEASES OF THE MIDDLE EAR, AND SOME OF THE BEST METHODS OF REMOVING THEM

Read before the Chicago Medical Society, August, 1887

BY GEO W WEBSTER, M D,
OF CHICAGO

That the nose, throat and ears are closely related anatomically, physiologically and pathologically is a fact that needs no demonstration at my hands But, that most of the non suppurative inflammations of the middle ear originate in the diseases of the nasal and post-nasal region is as trite a fact, but not as generally recognized by most practitioners And even many aurists have yet to learn that the way to most successfully treat many of these non-suppurative diseases of the middle ear and the resulting loss of hearing, is by a thorough, skilful treatment of the diseases of the nose and throat I know of few other conditions, in this line of practice, in which the results of surgical interference and treatment are more apparent and gratifying to both physician and patient, notwithstanding the fact that a well known author, in a recent work on diseases of the ear, says that the time spent in making a rhinoscopic examination is time lost

If an excuse for this paper be needed, it is found in the fact, as I have just stated, that all authors do not agree with me in the above statements, and also

that their truth, together with the utility of proper treatment such as I shall attempt to point out, is not always recognized, and, especially in our public institutions, does not receive the attention merited by the importance of the subject If I am right in my statements, it behooves us to recognize all the causes, direct or indirect, exciting or predisposing, that we may be able to treat them intelligently and in accordance with the modern ideas of pathology, and also to remove those causes capable of removal

Some of the principal recognized causes of non suppurative disease of the middle ear are about as follows Hypertrophies, of whatever nature, including hypertrophies of the turbinated bodies, pharyngeal tonsil, faucial tonsils, hypertrophic rhinitis, adenoid vegetations of the vault of the pharynx, exostoses and deviated and deflected septum, polypi, fibroid growths or any condition of the nose or throat that prevents free nasal respiration, also measles, diphtheria, typhoid fever, scarlet fever, indigestion, pregnancy, improper clothing, wet feet, bad hygienic surroundings, in short, any or all conditions which tend to induce and maintain congestion and inflammation of mucous membranes

The first principle in treatment should be to lessen the congestion and inflammation, and where they have terminated in hypertrophies, remove them The consideration of all these causes and conditions, and the treatment of each, would be material sufficient for many papers, and I will therefore confine my remarks to some of the first mentioned causes, viz those which interfere with free nasal respiration, beginning with hypertrophy of the turbinated bodies

In this condition we may have either a hypertrophy of the anterior end, the middle, the posterior end, or a general thickening of the entire turbinated body, and oftentimes a thickened, hypertrophied condition of the mucous and submucous tissues lining the entire post-nasal space In diagnosticating these conditions it is, of course, essential that we have a good light, a large head mirror or reflector, tongue depressor, small throat mirrors, nasal speculum, a fair knowledge of the normal appearance of the parts to be examined, the requisite skill and patience to make the examination, and a reasonably tolerant patient

For a tongue depressor I much prefer the modified "Tuerck" instrument, as it has a metal core for strength, is covered with hard rubber and does not corrode, is easily cleansed, and the short handle allows the little finger to rest in the hook at the end, giving a firm hold and a better control of the patient's head I much prefer a small rhinoscopic mirror except in very tolerant patients with very roomy throats In a small percentage of cases a palate hook will be of service, and is best tolerated if it be flat and wide I notice, however, that the more skill I acquire in making examinations the less frequently I make use of the palate hook

Hypertrophic rhinitis causes deafness by the hypertrophy extending to the mouths of the Eustacnian tubes, causing a thickening of the lining of the same either at the orifice or entire length of the tube, this tending to prevent entrance of air to the middle ear, and the air becoming absorbed, we have then the atmospheric pressure on the external surface of the drum head, tinnitus aurium, vertigo, sometimes adhesive inflammation, anchylosis of the ossicles, and variable degrees of deafness Then again, hypertrophy may, and often does, interfere with nasal respiration, and cause deafness, as follows

With every inspiration and act of swallowing we have, as Lucae has shown, a tendency to create a vacuum in the post nasal space, with a consequent congestion which must sooner or later result in thickening and hypertrophy of the mouths of the tubes, and then all the other phenomena just pointed out, with, in many cases, a total loss of the hearing power

Again we have, as has been shown by Weber Leil, of Berlin, a paralysis or partial paralysis of the palato tubal muscles, and this also tends to prevent the entrance of air to the middle ear in the normal manner Just how this paralysis is caused is not quite clear to my mind This condition can be easily diagnosticated as follows Adjust the catheter and attempt to inflate in the usual manner, and air fails to enter the middle ear Then direct the patient to phonate or swallow At certain movements of the palato tubal muscles the air enters suddenly, and again we fail completely, although we know "the catheter is in the proper position in the mouth of the tube" This Weber Leil explains by saying that the muscles have suddenly dragged open the mouth of the tube, and then as suddenly allowed it to close again I find that in these and many other cases I can inflate easily by pouring 2 or 3 drops of chloroform in the bulb of the ordinary Politzer apparatus This bulb I have had made of metal, as the rubber is soon destroyed by the chloroform

Again, I believe that the sympathetic system plays an important part in all these cases of catarrhal inflammation by its action on the blood vessels, but just what or how I do not know

Having examined our patient and finding him deaf, and then finding hypertrophy of the turbinated bodies and nasal stenosis, it is of paramount importance that we first restore free nasal respiration And how can this be best and most easily accomplished? Some authors use either chromic acid, nitric acid or acetic acid, others use tents, dilators, etc , others the cold snare of Jarvis, and others again give preference to the galvano cautery in some of its various forms, and this is my preference for all cases of hypertrophy of the turbinated bodies, as I believe it possesses advantages over any and all other methods at our command

The acids cannot be as well limited in action or confined to the exact points requiring their action, and cannot be made, in many cases, to burn deeply enough without burning laterally as well, and thus destroying too much of the Schneiderian membrane, and we cannot judge of the depth of the burn nor stop it when it goes deep enough, although I do not deny that good results have been obtained in some cases by the use of acids

Tents and dilators are little used now, and deservedly so, as they are, when used alone, of little service The Jarvis snare is as difficult to apply as the hot snare, is as painful, and requires sometimes sev-

eral hours for the removal of a growth after it has been firmly grasped by the loop, and there is, even then, much liability to hæmorrhage

The galvano cautery is easily managed, is convenient, its action can be limited, the degree, depth and width of the burn controlled, it is no more painful than the cold snare, and does, in a few seconds, the work that takes an hour or two with the cold snare, and does not give the same liability to hæmorrhage

The first point which I wish to emphasize is that if the growth is large enough to require removal, it can usually be removed with comparative ease with the galvano cautery loop, and if it cannot be grasped by the loop without the aid of pins, etc , it is not large enough to require entire removal and can then be cauterized, preferably with some form of "moxa" electrode In those large growths having a peculiar cauliflower appearance, anything less than complete removal is of very little value If, then, we find that we have a growth large enough to require removal, we apply a 10 per cent solution of cocaine to the growth For this purpose I employ a syringe with a long fistula tip, and then a bit of cotton wound on the tip Then with the aid of the milled nut we can eject a drop at a time, and this can be readily and conveniently applied only where desired

Having the loop ready, it is passed carefully back and over the growth, when, if careful measurements have been made, the growth can be easily engaged in the loop However, if we fail, we can sometimes adjust it by the aid of the rhinoscopic mirror By directing the patient to depress the tongue with the depressor we can hold the mirror with the left while we adjust the loop with the right hand This procedure is not always necessary, as I have frequently removed these growths without ever having seen them until after their removal, and having judged of their presence by the symptoms In these cases do not tie the palate forward, as it is very unpleasant and quite painful to the patient, is of little or no advantage to the operator except in rare cases, and is a barbarous procedure

Having adjusted the loop, it can be rolled in on the windlass with the thumb while we close the circuit with the index finger, and in a few seconds the growth is removed, as it usually adheres to the loop as it is withdrawn from the nose Very little hæmorrhage is likely to follow

If the growth be too small to require entire removal, and is smooth in appearance, I use either the "moxa" or the pointed electrode This is thrust into or through the growth and then the current made, and we thus destroy the submucous and vascular tissue with as little loss of the membrane as possible

In a third class of cases there is symmetrical hypertrophy of the entire turbinated body In these cases I have obtained the best results by a narrow deep burn extending the entire length of the turbinated body, and almost or quite to the bone Sometimes more than one line of cautery is necessary By this method the cicatrix resulting anchors the membrane firmly to the bone and prevents its puffing up, and at the same time cuts or burns through the enlarged blood vessels and thus destroys them

Any of these operations, and especially the last, is followed by considerable reaction and inflammation for about 4 or 5 days

In some cases the anterior ends of the turbinated bodies are enlarged to such an extent as to require removal It can best be done with the galvano-cautery loop I always use the platinum wire for my loops

Perhaps a word about the after treatment of these cases may not be out of place Twice each day the parts are thoroughly cleansed by the patient, using for this a hand atomizer with a modified Dobell spray, always warmed to about the temperature of the body or warmer Every second day I see the patient and cleanse thoroughly with the spray and post nasal syringe, and then apply soothing applications of vaseline or some vapor with the inhaler When the more acute symptoms have disappeared I apply cocaine to one side, and then apply a mixture of equal parts of tr iodine comp and eucalyptol, or solution of nitrate of silver, to the entire post nasal space I also apply the iodine and eucalyptol to the turbinated bodies in the same way, as well as to the mouths of the tubes when they are thickened Then the ears are thoroughly inflated, and if the mouths of the tubes are much thickened, I have derived some benefit from the alterative action of the negative pole with the galvanic current, the electrode being placed in the mouth of the tube, and always using a milliampère meter to exactly measure the strength of the current

If there be paralysis of the palate tubal muscles, the Faradic current applied in the same manner is of advantage

1922 Indiana Ave

MEDICAL PROGRESS.

THE ACTION OF CERTAIN DRUGS ON THE CIRCULATION AND SECRETION OF THE KIDNEY —In the Section on Therapeutics of the IXth International Medical Congress, DR CHARLES D F PHILIPS, of London, read a paper on this subject It contained a number of very interesting experiments, made with Roy's onkometer, with caffein, spartein, strophanthin, digitalin and ulexin [1] He concluded that the flow of urine is not so much dependent on the blood-pressure as on the rate of flow of the blood in the renal vessels With regard to this point, it is necessary to remember that, although such drugs as strophanthin produce a great increase in the *force* of the cardiac beats, yet these are very much slowed, so that it is quite possible that although the heart's action is stronger, yet the total amount of blood sent through any given organ, such as the kidney, in a given time, may remain the same Whereas such a drug as digitalis, producing as it does a rise of blood-pressure and a contraction of the kidney-vessels, may cause an increased quantity of blood to pass through the renal vessels On this view one

[1] Ulexin is an alkaloid from the gorse, *Ulex europæus*

could find the explanation of digitalin being a diuretic, and strophanthin not being one

Inasmuch, however, as spartein has not so marked diuretic action, we must also assume that digitalin must have some peripheral action on the secretory apparatus of the kidney

His results were tabulated briefly as follows, in three divisions

A Drugs that first contract, and afterward dilate the kidney

1 *Caffein*—in small doses—induces in the stage of contraction a fall of blood pressure—in that of expansion, a slight rise During the former, the flow of urine *may* be arrested, during the latter it is always increased, such increase depending on dilatation of renal vessels

(The possible *arrest* of secretion during the first stage is special to caffein, and may be induced by large or repeated doses)

2 *Ulexin*—gr ½—greatly raises blood-pressure during the first stage (that of contraction), in the second, expansion is much greater in degree but shorter in duration than under caffein, and is accompanied by brief but marked increase in urinary flow, the effective dose is limited by its toxic action on respiratory centres Practically, *excess* of caffein induces only the first stage—*excess* of ulexin only the second

B Substances that dilate the kidney, but to less extent and more slowly than caffein and ulexin, are dextrose, urea, sodium chloride, and acetate, and probably all constituents of the urine

C Drugs that contract the kidney without subsequent expansion

1 Digitalin, with *increased* secretion of urine (probably resulting from general heightened blood-pressure)

2 Spartein, with *diminished* secretion (in health at least)

3 Strophanthin causes slight temporary contraction, with no marked increase of secretion

4 Apocynein, similar temporary contraction, and no definite increase of secretion

5 Turpentine, 6, adonidin, and 7, barium chloride give similar results

In conclusion, it seemed to him that the plethysmographic method of experimentation is a valuable one for determining the exact action of drugs on the circulation, and one that deserves more attention than it has hitherto attracted —*Medical Record*, Sept 10, 1887

NEW METHOD OF TREATING DISEASES OF THE SKIN LOCALLY —In the IXth International Medical Congress DR VALENTINE KNAGGS read a paper on this subject He proposed as a substitute for ointments the employment of emulsions which upon drying on the skin form protective films He had employed these dressings for the past two years with gratifying results in eczemas and other non-specific exudations The inunction of the body with fixed oils has been found of immense service, but they are not adhesive, and exuding fluids readily escape from the surface There are two methods of rendering oily substances adhesive 1 By adding to them resinous, gummy, or alkaline substances 2 In making use of gums to combine or emulsify a fat with water

Adhesive preparations, unlike oils, tend to arrest skin-action Thus tar, varnish, or collodion form an impervious covering Ointments to which adhesive substances are added diminish skin action, but do not abolish it

Well-made emulsions resemble milk or cream, are soluble in watery fluids, and are markedly adhesive, and are made by combining an ointment basis with water, a vegetable gum, and a suitable antiseptic

Thus the formula preferred would read

℞	Paraffine molle	℥j
	Pulv gum acac	gr 160
	Boracic acid	gr 16
	Aquæ	ad ℥ij

Stir until emulsified

Bismuth, zinc, sulphur, or other medicament may be added as desired Smeared over the skin, a film is formed, which is flexible and protective, and the antiseptics and medicaments have the best opportunity of exercising a beneficial influence

The author called especial attention to the fact that all lint and textile dressings could be dispensed with He did not expect these gum emulsions to displace older methods, but that they would serve a useful purpose

DR UNNA said that we were now in the period of transition, making our annual change of treatment It was very well for us as specialists to discuss new treatments, but we should not give them to the general practitioner until we were quite sure that they were good, and especially should not confuse him with new treatments until we were quite sure that they were new He had worked much with fixed dressings and varnishes, and some years ago had described such a varnish as had the reader of the paper He was glad to confirm the reader's claim regarding the utility of the emulsion dressing, but could not concede to him that it was new, as there are many other varnishes made with gums and fats He did not believe that any varnish which is soluble in water can prevent a great amount of evaporation from the skin —*Medical Record*, Sept 10, 1887

VAGINAL EXTIRPATION OF THE UTERUS AND OVARIOTOMY —A very interesting account of this double operation is furnished by DR ROBERT ASCH, Assistant Physician to the Breslau Clinic The operation was performed by Prof Fritsch The patient, a woman of 42 years, was found to be suffering from carcinoma of the cervix, the history of which extended over a period of 5 months A further examination revealed the presence of an abdominal tumor about as large as a man's head To render the diagnosis clearer the patient was anæsthetized and the tumor was found to be either an ovarian cyst or a subserous myoma It was decided to first extirpate the uterus and then remove the tumor by a laparotomy

Before beginning the operation the vagina was thoroughly douched with a sublimate solution 1 2000

The peritoneum being reached it was found that the tumor had no connection with the uterus but that it was a cyst of the parovarium, as evidenced by the discovery of the enlarged left ovary, which was in relation with the pedicle of the tumor The uterus was removed without especial difficulty and a provisional iodoform tampon introduced The laparotomy was next undertaken When the peritoneum was reached it was observed to bulge forward and when incised air escaped, which had evidently found entrance to the cavity through the vaginal opening After removing the cyst and closing the abdominal incision the pedicle was drawn down and stitched to the vaginal wall The operation lasted 1¾ hours, and upon its conclusion the temperature and pulse were found to be very satisfactory The patient progressed well and after 8 days the sutures were removed and primary union was found to have taken place The vaginal tampon was removed and the vagina syringed out with a 2 5 per cent carbolic solution On the day after the removal of the sutures the patient felt so well that in spite of frequent admonitions she sat up repeatedly and as a result the abdominal wound opened The assistant physician being sent for found the wound open through out its entire extent Fifteen knuckles of small intestine, together with the transverse color and a portion of the omentum had escaped These were returned to the peritoneal cavity After most careful cleansing the wound was closed by 12 deep and as many superficial sutures The patient had considerable fever at first but the temperature fell on the fourth day and did not again rise above normal The patient soon convalesced Throughout the entire management of the case the strictest antisepsis was enforced Alcoholic stimulants including beer are freely used in the Breslau Clinic, together with coffee —*Centralbl für Gynak*, No 27, 1887

Lithium Carbonate and Sodium Arseniate in Carbonic Acid Water in Diabetes —Martineau recommends the following preparation Into an apparatus such as is commonly used in Paris for extemporaneously making carbonic acid water, are put twenty centigrammes of lithium carbonate and a tablespoonful of a solution of twenty centigrammes of sodium arseniate in 500 grams of distilled water The quantity of carbonic acid water used is about one litre This quantity is to be drunk by the patient during each day, either by itself or mixed with ordinary wine at meals

The simplicity of this remedy led Dr Austin Flint to test its efficacy in certain cases of obstinate diabetes which he had under treatment The ten cases reported led Dr Flint to the following conclusions

1 In the three severe cases in which the solution of lithium carbonate and sodium arseniate in carbonic acid water were used, no very marked effects were observed in the few weeks during which the remedy was employed, but the treatment seems to be worthy of more extended trial, and it may be useful in mitigating the severity of a strict antidiabetic diet.

2 The so called specifics for diabetes have little if any effect An exception, however, may be made in favor of the arsenite of bromine, which has sometimes seemed to control, to a slight extent, the thirst, polyuria, and discharge of sugar

3 The main reliance in treatment is to be placed upon an antidiabetic diet This has fallen somewhat into disrepute because it is seldom efficiently carried out In no single instance, out of 99 recorded cases, did Dr Flint find that the antidiabetic diet had been enforced

4 Milk should be absolutely interdicted Its influence over the progress of the disease is prompt, powerful, and most injurious

5 There are certain cases in which dietetic treatment promptly arrests the disease and keeps it under control There are other cases in which treatment seems to be of little avail, except in possibly retarding the progress towards a fatal result Of the ten cases reported, and now under observation, seven are amenable to treatment and three are obstinate

6 A confirmed diabetic may be cured, in the sense that all symptoms will disappear, but the disease is liable to return at any time under an unrestricted diet Still, moderate care in diet will often secure immunity

7 A patient who has once had diabetes should have his urine examined every few weeks The glycosuria always precedes the general symptoms of the disease, and these general symptoms can generally be forestalled by proper treatment employed as soon as sugar makes its appearance in the urine

8 As the disease returns, either from imprudences in diet or from other causes, the successive recurrences present greater and greater difficulties in the way of treatment —*Therapeutic Gazette*, Aug , 1887

Urinary Fistulæ —J Hohlmann reports the results of 35 cases of urinary fistula operated on in the Breslau clinic for women In 27 of these cases the fistulæ were produced by pressure of the fœtal head in patients with contracted pelves In 2 cases the pelvis was normal, but hydrocephalus was present In 5 cases they were the result of obstetrical operations Two cases were caused by operations for vaginal myomata One was caused by a calculus

Constipation was observed as a very constant symptom, the writer believes by the intimate relations existing between the innervation of the sphincters of the rectum and bladder The voluntary attempt to prevent the discharge of the urine results in an involuntary impulse given to the sphincter ani Menstrual disturbances were frequently noticed Fistula was *not* observed to occur more frequently on the left side The formation of fistulæ was found to be favored by the simple flat form of the pelvis as well as by the flat form with narrowing of all the diameters

Preparatory treatment consisted in 2 or 3 sitz baths daily in a 2 per cent solution of carbolic acid, together with disinfecting vaginal douches given in the recumbent posture Dilatation by Bozeman's method was not adopted Excessive tension on the vaginal walls was relieved when necessary by counter inci-

sions Silkworm-gut and silk were used for suturing 29 cases recovered, 6 remained unhealed In one case in which the fistula involved the ureter and vagina nephrectomy was performed and the patient recovered —*Centralbl fur Gynakol*, No 33, 1887

THE REMOVAL OF SMALL OVARIAN TUMORS — KUSTNER, of Jena, contrasts the difficulties attending the removal of small ovarian tumors with those which accompany the operations for the larger ones

1 The opening of the peritoneum is more difficult because the walls are not stretched The linea alba is harder to find because the recti muscles are not separated The incising of the supra-peritoneal fatty tissues is easier when there is a large tumor beneath

2 In small tumors the small intestines nearly always escape when the peritoneum is opened, a difficulty which seldom occurs in the case of large tumors, and then, as a rule, only when adhesions are present The prolapsed intestines obstruct the incision, and reposition is often an extremely difficult and tedious matter The hyperæmia which takes place in the prolapsed intestines leads to dysentery

3 The small size of the incision increases the difficulties of all manipulations

4 The pedicles of the smaller tumors are shorter

In spite of these difficulties the writer counsels operation as soon as the tumor can be recognized, preferring to operate thus early rather than wait, as advised by Knowsley Thornton in 1884, until threatening symptoms appear or until the tumor has reached the level of the navel Another argument in favor of early operations is that benignant ovarian tumors may become malignant On the other hand, it is often very uncertain whether a small tumor may not be carcinomatous or sarcomatous —*Centralbl fur Gynakol*, No 27, 1887

COCAINE ANÆSTHESIA —WOLFLER says that local anæsthesia can be always produced by the injection *into*, not under, the skin of a 5 per cent solution of cocaine This is also true for the inflamed skin, though the injection should not be made, as in cases of panaritia, in the inflamed region, but in healthy skin, and the needle only carried to the inflamed region In neuralgic conditions Wolfler has had very different results, in sciatica relief is only temporary, and in trigeminal neuralgias none at all He has seldom seen symptoms of cocaine intoxication, and for this amyl nitrite is the antidote

SCHUSTLER reports about 80 cases of cocaine anæsthesia for operations on tumors, herniotomies, circumcision, disarticulation of toes and fingers, etc He uses a 10 per cent solution, and lays stress upon the point that the injection should not be made under but *into* the skin, which should be rendered as bloodless as possible He especially recommends cocaine in such short operations as evulsion of nails, slitting fissure of the anus, rectum, etc In urological operations he has had but few experiences in Dittel's clinic thus far In a case of amputation of the leg, cutting through the soft parts was painless, but lifting the periosteum and sawing the bone were very painful, though the limb had been rendered bloodless

FRANKEL says that cocaine has no reciprocal but only a local action, but that very weak solutions, 1 per cent, are sufficient, and should be injected in as many places as possible He has used it in tumor extirpations —*Centralbl fur Chirurgie*, No 20, 1887

VESICO-UTERINE FISTULA, NEW METHOD OF CYSTO PLASTY —FOLET recently reported to the Société de Chirurgie of Paris the following operation Under anæsthesia the urethra was dilated until the index finger could be introduced into the bladder and the fistula felt Then an assistant drew the uterus to the vulva by means of toothed forceps, the mucous membrane of the portio was cut around on the anterior wall, and now separated, in the same way as in the first act of vaginal extirpation of the uterus, the wall of the bladder from the uterus on the side of the fistula The finger in the bladder served to control the vesical wall during this part of the operation, and pressed it down to the vulva The fistula was now accessible, and was sutured with catgut, the uterus replaced, and the vagina tamponed with iodoform gauze Recovery followed promptly and without the slightest trouble

Folet believes that this procedure—drawing down the uterus and pushing the vesical wall into the vulva with the finger in the bladder—may be useful not only in utero vesical but also in high lying vesical fistulæ, in which the freshening and suturing is difficult

In the discussion Verneuil said that in most cases of cervico-vesical fistulæ we can freshen and suture *in situ* by lateral splitting of the cervical canal In this way a large number of these fistulæ have been healed —*Centralbl für Chirurgie*, No 24, 1887

THE DURABILITY OF SUBLIMATE SOLUTIONS — PROFESSOR VICTOR MEYER, of Gottingen, has recently examined a question raised by Angerer, of Munich, that sublimate solutions in ordinary water, undistilled, may be made permanent by adding to the water an amount of common salt equal to the weight of the corrosive sublimate Were this the case of course it would be a matter of great importance in military surgery and in emergencies Angerer prepared tablets of definite amounts of sublimate and salt, which seemed to form as durable and as antiseptic solutions as those prepared with distilled water At the request of Konig Meyer made a number of experiments, which are detailed in *Centralblatt fur Chirurgie*, No 24, 1887 He used solutions of 1 1,000, as Angerer directed These were made partly with distilled water, and others with ordinary water The solutions were kept more than a month The results of the experiments show that with the precipitate, there is no doubt that salt has any considerable preservative action on the solutions in open or loosely closed vessels

VOLKMANN'S ANTISEPTIC LIQUID is composed of thymol, 1 part, alcohol, 10 parts, glycerin, 20 parts, water, 100 parts It is a useful formula for antisepsis by thymol —*Deutsche-Amerikanische Apotheker-Zeitung*, June 15, 1887

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

BACTERIOLOGY AND ITS RELATION TO SCIENTIFIC PROGRESS IN MEDICINE

The admirable address of PROFESSOR SEMMOLA, of Naples, to the Ninth International Congress, September 7, 1887, aims *first* to remind us of the true method of advancing scientific medicine, *second*, to show the fallacies and unproved assumptions of the prevailing bacteriological doctrines, and *third*, to more clearly develop the fact, that a study of the conditions of the living system favorable for the reception and propagation of microorganisms is of equal, if not greater importance than the study of the individual microbes In regard to the first he says "We affirm, then, that the experimental method in medicine has for its purpose, the determination of the phenomena of nature and their causes The experimental method admits no individual dogmatic authority, nor has it anything in common with the theories of hypothetical methods The individual loses his personal authority in comparison with the teachings of demonstrated science " Again he says "The problem assigned to medicine is very simple, to determine the conditions of vital existence and its phenomena in healthy and diseased organisms," and he asks "Which are the phenomena that the physician studies? The answer is the functional disturbance or symptoms of sickness What are the physical and chemical conditions of these phenomena?—The natural causes of sickness " And in all our studies he urges with much earnestness the necessity of rigidly adhering to observed facts and more complete investigations, instead of using isolated facts as the basis of most important pathological and therapeutic deductions, and saying truly that, "isolated facts are an idle and dangerous luxury, and in medicine, the isolated and scattered riches cannot produce by themselves useful progress in clinical study "

Under the second head he attributes the fallacies or hasty assumptions of the bacteriologists, to a departure from the true and more complete experimental method of research to which we have just alluded Thus he says "For more than ten years microbiology instead of advancing with measured and secure steps, pretends to become, itself, pathology It was a true whirlwind, enveloping all, and, at the side of precious discoveries like that of the bacillus of anthrax, of tuberculosis, and some others which are an honor to science, came forth from every part microscopical researches on the existence of new microbes in all diseases, and every sickness seems to have its true germ, destined, perhaps, to die before being registered " And he adds "Pathology has come to be proclaimed almost the same as bacteriology" In relation to the third division of the address we have space only for the following brief quotations "I have shown how bacteriology has exceeded its proper limits, and I now desire to call your attention to its detrimental influence upon pathology The true part played by bacteria in pathology is the production by them of certain noxious and decomposed elements of the blood, which substances, and not the bacteria, are the potent factors in the causation of disease The treatment of the physical and chemical constitution and conditions of the blood is a much more fruitful field for study and investigation than a direct attack by germicides upon the bacteria The human body in health is a laboratory in which are constantly conducted chemical activities of the most complicated nature, and this is doubly true in disease The action of the pharmacopœia may be best explained by the effect of the medicinal agents upon the chemical composition of the elements of the body " Again he says "The great facts of clinical observation transmitted through centuries, are the precious basis of modern medical science It is the duty of the physician, at present, to apply to those great stores of knowledge the clear light of the chemistry and physics of the present, and thus to deduce rules of action for the investigation of new facts and new truths which arise in the clinical observations of to day In such a manner only can we hope worthily to contribute through an extended period of time, to the solid structure of truly scientific medicine "

THE PERILS OF CIVILIZATION

To say that the people of civilized countries are daily subjected to dangers that the savage knows not of is but to state what almost amounts to a truism It is equally evident that those who travel and those who live in cities are subjected to more perils, and oftener, than dwellers in the country It is true that the savage incurs dangers that but seldom or never threaten civilized people, and he has no means of combating them except by his own prudence, will or strength The chief dangers of civilization, however, are not always, or in the greater number of cases, to be avoided by prudence, skill or strength of any one man They may be compared to a large army, and must be met as such by an army

Of the numerous dangers to life and limb which are the accompaniments of civilization and improvements, the greatest danger is from the railway train This is a danger which has been reduced to a minimum in Europe, where railways are the property of the various governments, as a rule From the populous condition of the countries of Europe it has been possible to, in all cases, build railways with double tracks, without wooden trestles, never crossing a public highway or another railway on the same level, and with the roadways fenced in and furnished with numerous track-walkers Long distances and the sparsely settled condition of our country have rendered these things most inconvenient and in many cases impossible in this country Single tracks, grade crossings, wooden bridges, trestles and culverts, and heating by stoves, cause in this country not less than 4,500 or 5,000 deaths a year, and very probably the number of deaths is in excess of these figures To this must be added the fact that for each person killed at least five are injured, temporarily or permanently There can, therefore, be no wonder that the Section on Public and International Hygiene of the Ninth International Medical Congress adopted the following

WHEREAS, The whole community has been repeatedly shocked by the almost daily occurrence of terrible accidents on many of our railroads, causing considerable loss of life, and by habitual neglect of most elementary sanitary laws,

WHEREAS, As this Section considers itself in a degree the guardian of public health, be it

Resolved, That the attention of this Ninth International Medical Congress be respectfully called to this most important question, and it be requested to use its influence to obtain the necessary reforms

How can these accidents be prevented, and what part can medical men take towards their diminution and prevention? They can only be prevented or greatly diminished by the making and enforcement of laws in the several States, by which severe penalties may be inflicted on railway officers and employés for carelessness, and which will compel all railway companies to be more careful in the construction of their tracks, in all the particulars mentioned In Germany, when a person is injured or killed by a railway accident, some one is almost sure to suffer for it The value of human limbs and life is too much disregarded in America We have recently had an example of this in Illinois, in which more than one hundred people were crushed to death, and many more injured, in the most frightful accident in the history of railroads And what has been done to make railway officials more careful in the future? The men chiefly responsible for the accident, which was caused by, it may be said, wilful negligence, are free and unindicted, while the coroner and his jury, those mockeries of civilization and intelligent examination, have endeavored to cast the blame on a poor laboring man, not responsible for the accident Over and over again has it been the case that high railway officials have compelled railway employés to testify falsely concerning the causes of fatal accidents by threats of discharge Of the many railways centering in Chicago every one comes in on a level with the streets, some running for miles through the city In very many cases there are no gates at street crossings, and no watchmen

In a previous issue of THE JOURNAL we have spoken of the injuries in railway accidents in winter from fires caused by the stoves in common use, and from the objectionable and dangerous methods of heating railway cars, and we think it has been shown that these things can be easily obviated

There are many other causes of injuries in large cities especially City health officers, while engaged in hunting up cases of infectious and preventable diseases, and nuisances of filth, run a constant risk, especially in Chicago, of breaking a leg by stepping into a defect in a sidewalk, of losing an eye by a chip of stone from a stone-cutter's chisel, or by a cinder from a passing locomotive or tug boat, or having an eye removed by the rib of an umbrella in the hands of a careless woman Our heads are often endangered by workmen who fail to place sufficient scaffolding around a building in course of erection Employés in high dark buildings are in constant danger from dark stairways, open freight elevator shafts, and the lack of fire-escapes in case of fire "Buddensieck" buildings continue to be erected All these things will continue until the law makes negligence and carelessness a crime

Since the profession is interesting itself and the public more and more every year in regard to preventable diseases, let us extend our interest to preventable accidents Little, perhaps, can be accomplished in six months or a year, but in time the labor will be rewarded Much can undoubtedly be accomplished by earnest and persistent efforts on the part of boards of health, even though a few silly newspaper writers declaim against "the curtailment of our liberties" The liberty to maim and kill should be curtailed

A CURE OF CHRONIC RHEUMATISM

"Cure of a case of chronic rheumatism of thirty-six years' standing," says MR CHARLES MAY, in the *Lancet*, of August 27, 1887, sounds so like a sensational heading of an account of the marvelous effects of some patent medicine that one almost hesitates to enter on a subject having such a basis But Mr May records a case, and one which is certainly interesting Four years ago he was called to see a maiden lady, aged 60 years, who had discovered that her right nipple was deeply retracted, so as to be quite level with the surface In addition to the cancer of the nipple he found that the lady had suffered for many years with rheumatism, which all treatment had failed to relieve The history of the case was that thirty three years previous to his visit, during very hot summer weather the patient sat between the open door and a window while in a state of profuse perspiration A severe attack of acute rheumatism followed, from which it took her three months to recover It is not known whether there were any heart complications at the time, but at the time of the visit the sounds were normal The joints were very painful and swollen, which condition never entirely subsided A less violent but sharp attack came on eight years afterwards, and again four and two years before Mr May saw her The last was more confined to the lumbar region, and very severe "During the whole of the long period named she cannot remember having been entirely free from pain Going up and down stairs (especially the former) was attended with pain and difficulty, and could not be accomplished without the help of the baluster, the process being very slow, step by step Out door exercise, except for a short distance leaning on an attendant, was impracticable Any attempt to walk alone immediately produced giddiness and a staggering gait, and if not supported she would fall to the ground A sharp pain was frequently experienced at the top of the sternum, which increased on any attempt to swallow, causing a choking sensation, consequently all fluids were taken by sips" There was no history of gout or rheumatism in the family, but a sister died of cancer

Mr May does not give a minute account of the treatment, which extended over a considerable time, but merely gives a general statement of the medicines given, and the gradual progress up to recovery From a general view of the case, the invasion and long-continued possession of the system by the rheumatic virus and the mammary glandular disturbance, he was led to select medicines having a specific action on the parts, and a depurative action He therefore began with the iodide and bromide of potassium, gr v of each, in compound decoction of sarsaparilla and decoction of buchu and broom To this was added gr iij of extract of conium night and morning, in deference to its influence on chronic rheumatism and glandular enlargements This treatment was continued for one year, simarouba and aromatic spirits of ammonia being occasionally substituted for the potassium and conium At the end of the year the swelling at the joints had subsided, and the patient was relieved of the heretofore constant pain She could also move about the house without the assistance needed before, though not freely, but she still could not take out-door exercise without assistance, and the giddiness continued The iodide was now discontinued, and the bromide and conium omitted every other week for three months, and every third week for the next three months, and finishing the year with simarouba "At the end of this time she had regained fair powers of locomotion, and could move about the house freely, going up and down stairs without help, and could take a short walk without support, but did not feel confident without a companion Six months after this there was no vestige of rheumatism, joints natural, pain quite gone Even that in the chest, which had interfered with her swallowing fluids except by small sips, was no longer experienced, the power of swallowing being natural Sleep was continuous from soon after retiring until the time for rising, a contrast to the pain and restlessness of former times The general health is now excellent To use her own expression, she 'scarcely knows herself,' for whereas during the whole thirty odd years she does not remember having been free from pain, she is now entirely free from it, and whereas she had been unable to move about the house or go out without assistance, she can go out by herself, and has walked four miles without a rest On a recent occasion she was in the park, when, looking round to see that no curious eyes were watching her,

she said to a relative who was with her—'Don't laugh, I am going to run,' which she did"

The case recorded by Mr May must certainly be looked upon as very remarkable, and not the least remarkable points about it are, that a patient was found who would follow directions for so long a time in a case so apparently hopeless, and that the drugs given could be continued for so long a time without producing other than the desired effects Only twice was it necessary to discontinue the iodide on account of the catarrhal symptoms Conium was discontinued for a short time on three occasions, not from evidence of toxic action but because it was thought prudent to discontinue it The case further shows that if we would produce good results by drugs in such cases it must be by long and continuous administration

SUPRAVAGINAL AMPUTATION OF THE GRAVID UTERUS FOR MYOMATA

The first supravaginal amputation of the gravid uterus for myoma, on a basis of definite indications, was done by Kaltenbach on March 2, 1880 The case was that of a woman, 32 years old, who had aborted once An abdominal tumor was found which reached almost to the navel Later, when the tumor had reached the region of the stomach, the patient was examined under an anæsthetic, and was found to be in the 4th or 5th month of pregnancy Many small fibromata were found, and on the left side a fibrous tumor with a broad base, which was larger than the uterus Supravaginal amputation was performed with satisfactory results, the tumor weighing 3,350 grams, and showing on its interior several spots of softening According to Kaltenbach the operation has since been performed 9 times since then, with 3 fatal results His second case was that of a woman 33 years old, who had aborted once, there being a history of severe hæmorrhage extending over 4 years A fibromyoma as large as a child's head was found in the interior of the uterus Three years later the tumor had so increased as to render an operation necessary, and when removed the tumor was found to be as large as a gravid uterus at the 8th month The stump was treated *extra peritoneum*, and a 50 per cent solution of chloride of zinc used Softening of the interior of the tumor had taken place The patient made a good recovery

VOGEL has operated 11 times, and he contributes a paper on the subject in a recent number of the *Centralblatt fur Gynakologie* According to Kaltenbach and Vandrin the maternal mortality after this operation thus far is 50 per cent But in the 11 cases reported by Vogel the mortality was only 27 3 per cent The oldest method of treatment is that of inducing abortion or premature labor, with the idea of relieving the crowding of the abdominal viscera, and giving the tumor time for retrograde metamorphosis Vogel discards this method, however, on account of the dangers of hæmorrhage and infection The operative measures are myomotomy and supravaginal amputation By the first the woman is relieved of the tumor, and the child is given a chance for life This operation can be performed in cases of subserous and interstitial myomata by enucleation In cases of multiple myomata of the uterus attended with rapid growth or dangerous symptoms (threatening life) supravaginal amputation alone is to be considered

SOCIETY PROCEEDINGS.

CHICAGO GYNÆCOLOGICAL SOCIETY

Regular Meeting, Friday, April 15, 1887

THE PRESIDENT, CHAS WARRINGTON EARLE, M D, IN THE CHAIR

(*Concluded from page 444*)

ANTISEPSIS IN ABDOMINAL OPERATIONS, SYNOPSIS OF A SERIES OF BACTERIOLOGICAL STUDIES

The Preparation of the Sponges, Silk, Instruments, Gauze and Water—The sponges were those prepared by Schorse, of Milwaukee The silk was boiled an hour in a 5 per cent carbolic acid solution, and in some cases afterwards immersed in a solution of iodoform and ether and again sterilized by moist heat in a bottle stopped with cotton This was done by placing the bottle in a pail containing an inch of water and boiling for an hour The instruments were boiled an hour in a 5 per cent carbolic solution on the day before the operation and then dried On the morning of the operation they were again boiled for a few minutes in a similar solution and placed in trays of sterilized water for use

The water was sterilized by boiling in large tin cans, each holding 2 or 3 gallons, for an hour or more on three successive days The cans had tin covers, put on over a rim of cotton to stop the crack between itself and the can

The culture medium used for these investigations was sterilized, alkaline, peptonized beef tea gelatin Most bacteria will grow in this medium at the temperature of a living-room Answers have been sought through these investigations to the following questions

1—Are the sponges sterile when rinsed out and ready for use?—Pieces of each of the sponges to be used were cut off by the assistant who had the care

of them and put into the gelatin with sterilized forceps Three or four pieces were put in a single tube In this tube you see three such pieces surrounded and permeated by the transparent nutrient gelatin Out of twenty-five sponges from seven operations only a single sponge was found infected with a single colony Through attempted cultures from these prepared sponges and silk, answers to the following questions have been sought

2 —*Are the sponges sterile when ready for use?*—After the sponges had been rinsed out in sterilized water three times, the assistant cut off small pieces from each of the sponges to be used with scissors, and they were put in a tube of liquefied gelatin beef broth This tube contains three such pieces of sponge surrounded by the clear solid gelatins Out of twenty-five sponges from seven operations only a single sponge was found infected with a single colony

It appears that the sponges are sterile at the beginning of the operations and if sterile then of course aseptic Five or six pieces of silk were usually taken from as many needles, and an inch cut off from each and put in a single tube of gelatin More than thirty such pieces were examined from nine operations, and not a single colony developed In no case was the silk infected at the beginning of the operation

3 —*Is the catgut sterile? (Schorse's carbolized catgut)*—Several pieces at four operations were examined In one case only did any colonies develop In this tube you see two pieces of catgut at the bottom of the clear gelatin Clinging to the side of one piece you can discover a small spherical white colony, and a little distance from it in the gelatin another similar colony This catgut was from a new bottle of catgut used in operation 5, in a private house in the country It is difficult to say how significant their presence is They might arise from any one of the following causes

1 Imperfect primary sterilization of the catgut

2 Infection by floating germ or germs from the hands of the assistant when unwinding and cutting off pieces

3 Infection through transportation to and from the country

4 Imperfect sterilization of the nutrient medium

It is my own opinion that it is from infection through the second of the above named causes

Thus out of over thirty tubes containing over sixty pieces of material taken before the operations, only *two* pieces were found infected with *three* colonies This would indicate that the precautions taken are very successful at the beginning of the operation

4 —*Are sponges sterile after they have been used?*—At the end of each operation small pieces of each of the sponges used were cut of and placed in gelatin in the same manner as at the beginning They were usually stained with blood, and sometimes had pieces of the contents of the cysts clinging to them Thirty pieces from eight operations were thus examined In the tube which contains two pieces of sponge from the last operation, No 8, are numerous colonies on the side of the upper sponge They are spherical and whitish, and do not liquefy the gelatin The following is the list of the sponges infected

Operation 1, 5 sponges examined, 1 infected
Operation 2, 2 sponges examined, 1 infected
Operation 5, 4 sponges examined, 1 infected
Operation 8, 2 sponges examined, 1 infected

The sponges were generally sterile at the close of the operation, even though most of them had come in contact with the skin of the abdomen and the contents of the cysts

It may seem strange that the sponges used in operation 4, pyo salpinx, in which the cyst burst into the abdomen, in tearing it away from its adhesions, did not develop any colonies Five sponges were examined, and all remained apparently sterile From the pus in this cyst (cultures) were made in solid blood serum with the growth of a small micrococcus usually in the so called diplococcus form, but this microbe would not grow in gelatin beef tea

5 —*Is the silk sterile at the close of the operation and after it has been used as sutures?*—Out of twenty pieces of silk, often cut from the ends of abdominal sutures, only a single piece was infected with a single coccus form, viz one of the two pieces taken from operation 1 Over fifty pieces of material, after being used in operations, and only five pieces—four sponges and one piece of silk—were found infected It does seem, therefore, that the sponges and silk may be maintained sterile, so far as any germs that will grow in nutrient gelatin are concerned, even to the end of a long operation

In marked contrast to these results appear those from an operation performed by another operator who kindly allowed similar examinations The details of the preparations were given for publication The operating room was well washed with soap and water, both walls and floor It was in a new house which had never contained a sick person The sponges were part new and part old, having been used in a previous abdominal section After that operation they had been soaked a day in a strong solution of bicarbonate of soda, and washed out in a 5 per cent solution of carbolic acid and hung away in a bag On the day before the operation all the sponges were boiled in a porcelain kettle for more than an hour in a 2½ per cent solution of carbolic acid, and put into a jar and taken to the operating room The silk was boiled and carried in the same jar The operator took a bath and put on perfectly clean clothes on the morning of the operation The assistants were instructed to do the same The hands and arms of the assistants were washed in soap and water and then in a sublimate solution 1-1000

The material examined consisted of four sponges and two pieces of silk before the operation, after the sponges were rinsed out, and the needles threaded, and of two sponges after the operation and several inches of the thread used All the material was infected except one piece of silk examined at the beginning of the operation Every sponge had at least one colony of the hay bacillus, and one sponge after use showed more than fifty small white colors in the clear gelatin in the upper part of the tube

What influence the asepsis of the material has on the results of the operations as to death or recovery

is a question far beyond the scope of these investigations It would require a large statistical material of well observed cases, and more work than could be done by one observer But it may be safe to conclude that it is desirable to work through an abdominal operation with perfect asepsis everywhere, if such a thing is possible The above investigations have shown that such perfect asepsis can be attained Thus if we are ignorant of the extent of danger from non sterile material, we are hardly justified in trusting to the innocence or inocuousness of such an uncertainty, while we can have the asepsis of the material an absolute guaranty against the dangers of infection

Operations performed by Dr Christian Fenger

1 Dermoid of ovary Emergency Hospital, November 9, 1886 Bursting of cyst into the abdomen during operation, irrigation, 1 sponge and 1 piece of silk infected after operation, 4 tubes used to examine 12 pieces of material Recovery Development of properitoneal abscess, which was opened in the sixth week Complete recovery

2 Cysto-sarcoma of left ovary Emergency Hospital, November 30, 1886 Solid movable tumor 6 inches in diameter, only slightly adherent to abdominal organs, metastasis in peritoneum, some ascites present Drainage, 6 tubes used to examine 11 pieces of material, 1 sponge before use and 1 sponge after use infected, each with a single colony Recovery

3 Radical operation for hernia Emergency Hospital, January 18, 1887 Eight tubes used to examine silk and sponges and catgut, all sterile Recovery

4 Pyo-salpinx Emergency Hospital, January 19, 1887 The sac, adhering on all sides, ruptured in removal Irrigation of abdomen, 14 tubes of nutrient gelatin used, all sterile *Contents of cyst planted in solid human blood Serum developed diplococci of very small size, which do not grow in gelatin*, probably gonococci Death from acute sepsis within 48 hours

5 Double dermoid Private house, January 24, 1887 The tumor of the left side had ruptured 20 years before, and produced an almost fatal peritonitis (?) This tumor was now large and adherent all around The tumor on the right side was small and free, 9 tubes used with 25 pieces of material, 1 piece of catgut infected with 2 colonies, 1 sponge infected with a single colony Death from shock within 12 hours

6 Cyst of ovary Emergency Hospital, February 3, 1887 Seven tubes used to examine 10 pieces of material, all sterile Recovery

7 Cyst of ovary Emergency Hospital, March 22, 1887 Two tubes used to examine silk and sponges after operation only, all sterile Recovery

8 Malignant cyst of broad ligament County Hospital, March, 1887 Four tubes used, all sterile Death from uræmia on the fifth day Autopsy Atrophic and dilated kidneys

9 Proliferating cystoma of ovary Emergency Hospital, March 24, 1887 Large and adherent, burst during removal Irrigation of abdomen to remove cyst contents Drainage, 5 tubes used, 12 pieces of material, only 1 sponge infected with numerous colonies Death after 36 hours Autopsy after 6 hours Thrombosis of right ventricle Bloody serum found in the peritoneal cavity in small quantity was added to nutrient gelatin It remained sterile after 2 weeks' incubation

Contrasted case performed by another surgeon in which less successful antiseptic precautions were used

Cysto sarcoma of ovary Private house, February 22, 1887 Very large, and adherent to omentum and abdominal wall Drainage by means of 2 rubber drainage tubes, 9 tubes used for silk, and sponges all infected except one, containing silk, before the operation The sponges, after use, contained many 50–100 colonies Each of the 8 infected tubes had at least one colony of the hay bacillus Death on the third day No autopsy At each daily dressing there was evidence of some oozing from the drainage-tubes

DR CHARLES CALDWELL read a paper on

ENLARGED THYROID OR GOITRE, A CAUSE OF TRANSVERSE PRESENTATION

June 1, 1884, Mr G summoned me to attend his wife On the way to the house he informed me that she was in labor, that a midwife was in attendance and had been for 24 hours, that his wife did not seem to be making any headway, but was becoming weak and exhausted, and the midwife was frightened, not knowing what was the cause of the delay or what to do Her condition upon my entrance was truly frightful She was in the midst of a labor pain, pulling the midwife's hands, straining every muscle, her whole face cyanotic, and her eyes protruding as if they would escape from their sockets Exhausted she fell back, gasping for breath It required but a single glance to perceive that death threatened this poor woman from two sources, *i e*, asphyxia and rupture of the uterus Bimanual examination revealed the fœtus in a transverse presentation The os was fully dilated and the membranes had ruptured The mother had not felt the movements of the fœtus for several hours and its heart sounds could not be heard Podalic version was performed without delay, by Braxton-Hicks' method The feet were brought down, and during the next labor pain the second stage was completed The third stage consumed but a few minutes and the uterus contracted well The fœtus was large, but showed no signs of life The heart's action had probably ceased several hours before After visiting my patient for three succeeding days, during which time her pulse and temperature remained normal, I saw no more of her, but her husband, whom I met the following week, informed me that she got up the fourth day and attended to her usual household duties

October 16, 1885, I was called a second time to attend Mrs G in labor, and as in the first instance, she had called a midwife, also as before, she had been under her tender care, or rather at her tender mercy, for 24 hours Again the fœtus was in a transverse presentation with the right arm and prolapsed cord protruding from the vulvar orifice, for the membranes had ruptured The cord was pulseless The hand and arm were easily pushed up over the face

and above the brim of the pelvis By combined manipulation, with the right hand in the vagina and the left over the abdomen, cephalic version was performed The head was brought down into the first position and held there until by a strong labor pain it became engaged, when forceps were applied at the superior strait and the fœtus extracted during the next pain This fœtus was an unusually large one, and I regret it was never weighed Dr Jaggard, who utilized it for the cause of obstetric science, says it must have weighed nearly or quite 20 lbs Her puerperium was normal as before, which means she left her bed the fourth day

February 18, 1887, Mr G , for the third, and I hope the last time, summoned me and said his wife needed my services again that this time they had decided not to call a midwife first, but to send for me at once and give me a better opportunity to save the child's life Examination revealed a third case of transverse presentation Os was fully dilated, but membranes unruptured Through the membrane, by vagina, could be felt both the feet and hands The head was to the right and breech to the left Fœtus was in dorso posterior position The placenta could be easily felt through the abdominal walls, and was attached to the anterior wall of the uterus, near the fundus By external manipulation, I attempted to perform cephalic version before the membranes ruptured The amniotic fluid was small in quantity, and I failed Deciding upon podalic version, the membranes were ruptured, and a fœtus weighing 12 pounds was delivered in a few minutes, but not without considerable muscular exertion on the mother's part as well as on my own

As I brought down the feet with the right hand and pushed up the head with the left, the abdomen of the fœtus rotated anteriorly As soon as the body was delivered, I clasped the thorax of the fœtus with the left hand to prevent inspiration and asphyxia The arms were then brought down, and with the assistance of the nurse, who raised the child's body up over the mother's abdomen, I seized the fœtus by the occiput and delivered the after coming head without forceps The child gasped a few times, and then began to cry, to the delight of its mother Placenta was soon expelled and the uterus contracted firmly and well Puerperium as in the two preceding cases

This patient was born at Konigsburg, Germany, in 1852, was married in 1873, and is the mother of ten children The oldest four were born in Germany —the others in America during the last nine years Her first seven confinements were normal and she was attended by a midwife Seven years ago the left lobe of the thyroid gland began to enlarge during gestation, but caused neither pain nor dyspnœa Three years ago, during her eighth pregancy, the right lobe began to enlarge, and increased in size very rapidly, producing both pain and dypsnœa, compelling her to take a semi recumbent position at night instead of a horizontal one During the last three months of gestation she sat bolstered up in bed at night This posture, which she was obliged to take whenever she sat down, during the day as well as the night, produced a continued pressure on the fundus of the uterus, changing its long axis from a vertical to an oblique or transverse direction Of course, the long axis of the fœtus must coincide with that of the uterus, and the continued pressure on the breech or head, according to the end of the fœtal ovoid at the fundus, would force it into an oblique or transverse position, and also throw the lower end of the fœtus out of the pelvis and above its brim The same position of the mother is maintained during labor as during the last three months of pregnancy, hence the fœtus remains in the same oblique or transverse position, and the lower end of the fœtal ovoid cannot descend below the pelvic brim

It seems to me the above facts explain perfectly why the fœtus has been found in a transverse position, the three last confinements, and never at a previous one

In examining the obstetrical treatises at my command, I find no mention of enlarged thyroid as a cause of this presentation, but that it certainly is in this case I have not the least shadow of a doubt The causes usually given are Immature fœtus, contraction of pelvic brim, laxity of uterine muscles, excessive liquor amnii, twin pregnancies, etc , all of which can be excluded in this case The case has been quite interesting to me, for it is rare in my obstetric practice to meet with cases of transverse presentation, and I have *never* before seen it occur three times in succession in the same patient I saw my patient last week, and find by measurement of the tumor at the largest point, that it has diminished more than an inch in its circumference in seven weeks, and that she can now sleep in bed with two pillows under head Dyspnœa is not alarming until the seventh month of pregnancy, but fron that time until confinement it is excessive This is hardly the place to discuss what mode of procedure should be followed in her case for her relief, and yet, as she is but 35 years old, it is very probable that she may become pregnant again, and possibly lose her life, if nothing is done to remove or at least reduce the size of the tumor, until it shall cease to be a source of such alarming dyspnœa

I should be glad to hear the opinions of any of the Fellows who have had experience with this class of glandular tumors From my own experience I should not be in favor of total extirpation, for I once saw a woman cross the river before the operation was completed Ligation of the superior and inferior thyroid arteries, partial resection, injections or electrolysis seem to offer better results, and are certainly much less dangerous

Dr D T Nelson I have had one patient that this case reminds me of, in which not shoulder or other irregular presentation was the cause of difficult labor, but a high promontory (and it seems to me with the experience I have had with abnormal presentations that a high promontory is a very common cause of mal position), complicated by an enlarged thyroid, not to the extreme extent of the case reported, but such as to give the patient a great deal of inconvenience in the last months of pregnancy, and especially at the time of delivery I have delivered her with instruments several times The treat-

ment I have adopted in her case for the enlarged thyroid, and with seeming benefit, has been the free use of ergot in the intervals between pregnancies The gland will diminish greatly in size, at least in the intervals between pregnancies, as the pressure is taken off the circulation When she followed the treatment with some degree of faithfulness (she would not use the remedy with persistency), it seems to me that in two periods, when she did fairly well, continuing it for about two months, there was a more marked improvement than at any other time I would suggest this to the Doctor, as I know of nothing else that is more likely to serve him, before he decides upon a surgical operation In the acute enlargement of the thyroid, occurring in both sexes at puberty, though most frequently in the female, I have given ergot with excellent results, continuing it several months

DR C T PARKS I would suggest as to the treatment of this thyroid gland, that among the many methods I have seen adopted, the injection of a 5 per cent solution of carbolic acid sometimes brings about a very rapid improvement, and decrease of the enlarged gland An injection with a hypodermic syringe once or twice a week is not followed by any unpleasant reaction

SUFFOLK DISTRICT MEDICAL SOCIETY

SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE

Stated Meeting, May 11, 1887

DR F L KNIGHT, CHAIRMAN

ALBERT N BLODGETT, M D, SECRETARY

DR F W STUART read a paper entitled

CAN CIRRHOSIS FOLLOW TRAUMA? A MEDICO-LEGAL QUESTION

October 3, 1885, during the service of Dr E O Otis, J B, aged 10 years, came to the Carney Hospital His family history was good He had always been well up to 1882, when he had an abscess on the left side of his neck which suppurated for two years, and resulted in contraction of the left side of the neck He had visited the Carney Hospital in June, 1885, when the following note was made "Patient listless, loss of appetite, diarrhœa three days, contraction of sterno-mastoid on the left side due to an old abscess, tenderness over the site of the old gland and in the region of the pneumogastric" The patient complained only of swelling of his abdomen He was very irritable, and cried so much that it was impossible to make a careful physical examination, though it was evident that there was fluid in the peritoneal cavity, fluctuation being well marked He was given syrup ferri iodidi, and told to return the next day for a careful examination The patient returned Monday, October 5, Drs E O Otis, W H Devine and myself being present We were now told that on the previous Tuesday the patient had been kicked by a schoolmate, and that the disease dated from the day of the assault A careful history was now taken, and a thorough physical examination made The patient's mother stated that he had always been well up to the time of the assault, with the exception of the abscess and the attack of indigestion mentioned before She said that he was nervous and irritable, but attributed this to the fact that the boys of his age were constantly irritating him on account of his wry neck Otherwise he was a strong, healthy and cheerful boy On Tuesday, September 29, while playing in the street he became involved in a disturbance with a schoolmate, and, though an exact story of the quarrel could not be obtained, it was established that the patient had been knocked down, and while lying on his back had been stamped upon, the heel of the assailant striking him in the abdomen The patient spat up some blood, walked into his house not far away, complained some of pain, but the next day was able to attend school On the Saturday following, his mother first noticed that his abdomen was swollen, and brought him to the hospital

Physical examination showed the patient to be well developed for a boy 10 years old, but he was decidedly pale and cachectic in appearance His temperature was normal, and his pulse and respiration were but little hurried Heart and lungs were normal His abdomen was much enlarged and fluctuating On percussion there was dulness everywhere, with some areas of flatness, and the percussion note was unaffected by a change in the patient's position The urine was high colored, specific gravity 1021, albumen ⅛ per cent, and the sediment contained some renal epitheleum, urates and a few casts The existence of an exudation, was of course, very evident, and a diagnosis of chronic peritonitis was easily made, but at the same time it was felt that there must be something underlying the peritonitis In attempting to diagnosticate the disease more accurately, some differences of opinion were developed, though it was considered to be very probable that the case was one of tubercular peritonitis The absence of any tubercular trouble in any of his relatives, as well as the absence of any pulmonary signs in the patient tended to negative this view

In a few days the distension became more marked, the genitals were very œdematous, and the breathing became embarrassed On October 16, the abdomen was aspirated, and about two quarts of a clear serous fluid were drawn off, it being impossible to aspirate more than a small part of the exudation, owing to its being sacculated At the same time the genitals were punctured with a needle and the fluid allowed to trickle away During this time the patient bled very frequently from his gums Under symptomatic treatment the effusion largely disappeared, and the patient was able to attend school again This improved condition lasted for some time, after which the fluid began to reaccumulate, and a scrotal hernia was developed on the left side

Again there was improvement, and in May, 1886, the patient returned to the hospital to see if something could not be done for his neck Examination

at that time showed still evidences of the exudation, and the borders of the liver and of the spleen were undeterminable

July 3, the boy who assaulted our patient was tried in the police court on the charge of having committed a felonious assault, and I was the only medical witness summoned The facts were testified to as stated above, though the testimony also unintentionally drew out the information that the patient had for months been subject to bleeding from his mouth I was asked whether in my opinion the kick received caused the patient's disease I answered that I thought that the injury did not cause the existing trouble in the sense of starting it up, *de novo*, though I admitted that possibly it might have hastened a previously existing disease

My conclusion was based on the following considerations It did not seem to me that the injury had started up an acute peritonitis, because the patient was not very sick, that is, he had not been confined to his bed, he had no marked fever, and had not complained much of pain Furthermore, it seemed to me that so large an effusion thrown out in four days would have perceptibly embarrassed his respiration and quickened his pulse Therefore it seemed to me that the assault merely served to call attention to a previously existing condition, which it at most had aggravated

The question then asked was Could the hernia be due to a weakening of the abdominal walls at the point of the injury induced by the kick? I thought not, and attributed the hernia to simple distension of the abdomen by the fluid

Finally, I was asked if the spitting up of blood was not proof that the kick had caused some internal injury I answered decidedly, no The patient may have received a blow on the mouth, may have bitten his tongue in falling, and in any event this symptom could have but little weight in determining the force of a blow in one who so often before had "bleeding from his mouth" The defendant was, however, bound over to the Superior Court, and a hearing before the grand jury resulted in the finding of a true bill

July 25, Dr Devine was called to see the patient, and afterwards Dr Otis saw the case with him The patient then had great distension of the abdomen and general œdema Tapping was advised, but not consented to by the parents

August 4, the patient complained of great pain in his abdomen, his pulse was rapid, temperature high, and the general constitutional disturbance great Dr Devine, who was then attending the patient, attributed these symptoms to an acute exacerbation of the peritonitis The patient died August 6, and an autopsy was made by Dr F W Draper, Medical Examiner, at 2 45 P M of the same day Drs Devine and myself being witnesses Dr Draper has very kindly sent me the notes of the case, which were as follows

Autopsy by Dr F W Draper, Medical Examiner, at 2 45 P M, August 6, 1886 Body very pale, a little livid discoloration of dependent parts Rigor mortis absent No appearances of decomposition

General anasarca—œdema of face, arms, hands, thorax, abdomen, genitals, legs and feet Abdomen distended with fluid, fluctuation well marked Scrotum large and red At the left inguinal ring, there was an opening sufficiently large to admit the index finger easily

Internal Examination —The peritoneal cavity contained 172 fluid ounces of clean, thin, serous fluid The heart was normal The lungs were œdematous and injected in their lower and posterior portions The spleen was enlarged to four times its normal volume, it was softened and its section presented limited areas of diffuse hæmorrhage infiltration The kidneys were moderately enlarged, pale, with normal relations between the cortical and medullary portions, their capsules were free The liver was reduced to the size of a man's fist, it was of very dense consistency, light yellow color, with thick interstitial partitions between the lobules, and a great number of small nodules upon its surface The intestines and apposing surfaces of the abdominal organs were firmly adherent at numerous points by strong bands representing a former inflammation of the peritoneum, and layers of soft lymph at various situations indicated more recent peritonitis The peritoneum was thickened and opaque There was no purulent exudation The peritoneum and mesentery were œdematous, and the dependent parts of the intestinal folds showed limited patches of hæmorrhagic infiltration The stomach and intestines presented nothing remarkable upon internal examination The mesenteric glands were normal The brain was soft and œdematous

Diagnosis —Chronic interstitial hepatitis, chronic hyperplasia of the spleen, chronic adhesive peritonitis, ascitis and general anasarca

Cirrhosis of the liver is so rare a disease in childhood that many of the books specially devoted to children's diseases make no mention of it Still, in a very hasty review of the literature on the subject, limited to the usual reference books, I find quite a number of recorded cases

F Weber[1] and Virchow[2] report congenital cases, Wettergreen[3] reports a case at four, Cayley[4] and West each one at six, Loeschner[5] one at seven, Hauerwas[6] and Wilks[6] each one at eight, Murchison,[4] Frenche[7] and Griffith[4] each one at ten, Maggianni[8] one at eleven, Steffen[8] two cases, one eleven the other thirteen, and Wunderlich[8] observed two cases in sisters, aged eleven and twelve years respectively None of these are recent cases, since I did not have time to consult the recent journals

It is generally admitted that the excessive use of alcohol is the usual cause of cirrhosis, but various others have been given Flint mentions syphilis, chronic malarial poisoning, chronic phosphorus poisoning, chronic peritonitis, and occlusion of the bile duct as causes to which cirrhosis is often assigned,

[7] Quoted by Pepper
[8] Quoted by Niemeyer

though he would doubt the efficiency of them The excessive use of condiments and extension of a perihepatitis have also been charged with producing cirrhosis, while Griffith in the report of his case, alluded to chronic abscess as if it were a recognized cause of this disease Of the cases cited, Wunderlich, Murchison and West (the latter a patient, a girl of 8, being in the habit of drinking a half pint of gin daily) were able to prove that their patients had used alcohol to excess Wettergreen and West attributed their cases to the excessive use of coffee The writings of Virchow and the reports of the Italian physicians would lead one to believe that syphilis and chronic malarial poisoning may cause cirrhosis, but in the main one is almost forced to look upon this disease as a specific disease with its specific cause—alcohol The reader has notes of a case of cirrhosis seen in Professor Bamberger's ward in Vienna The patient, a girl 11 years old, gave a history of intermittent fever, and to this her disease was attributed But long after she had been admitted to the hospital it was ascertained that her father kept a "Brantwein-Geschäft," thus making it, after all, more than probable that her trouble was due to alcohol, since in the family of such a man brandy was likely to be looked upon as a panacea for all our ills It must, however, be admitted that careful questioning fails to establish an alcoholic habit

What caused the cirrhosis of the liver in our patient? Did the trauma cause it? There was no history of the abuse of alcohol, there was no question of syphilis, since parents, and brothers and sisters were all healthy and free from any signs of this disease, and the patient had never had intermittent fever If the injury caused the disease, it first started up a chronic peritonitis, and secondarily to this came the cirrhosis That such a thing is possible has been suggested, but I think it hardly probable, and in this case I feel that in June, 1885, when the patient was listless, etc , and a diagnosis of indigestion was made, he had beginning cirrhosis

This would coincide with the opinion arrived at from his physical condition when I first saw him, that his disease dated back weeks at least According to Griffith, the chronic abscess may have caused it, but I failed to see the report of any case tending to support such a view In conclusion, let me say that I believe it wiser to admit our ignorance of the cause involved in a case so puzzling, as this, than to refer it to so hypothetical a cause—as a chronic abscess

DR A N BLODGETT said that the insidious character of the disease in the present case, its great gravity, and its fatal termination forcibly reminded him of a case seen at a distance from Boston, in which a somewhat similar and equally unusual course of phenomena were noticed The patient was a literary gentleman, well known to many members of this Society, who while in the enjoyment of his ordinary good health, was surprised to find that he was becoming weak, and particularly that he was troubled by shortness of breath on making any exertion, sometimes experiencing almost the condition of asphyxia After a time he sought medical advice, but was able to give absolutely no satisfactory history of the character of his disease Physical examination revealed the fact that the left side of the thorax was the seat of an extensive pleuritic effusion, the liquid reaching to the level of the sixth rib in the nipple line Twenty-four hours later, the fluid had increased to such a degree, that there was constant oppression in breathing, and the level had risen to the fifth rib in the axillary line The case was diagnosticated according to the rational and physical signs, as acute pleurisy, but was considered peculiar from the entire absence of any of the ordinary symptoms of this disease The case passed into the hands of a very distinguished practitioner, who treated the patient by the constant exhibition of alkalies, and frequent and abundant catharsis, without, however, any attempt to relieve the distension of the pleura by aspiration or puncture, and the patient rapidly sank, and died at the end of four days The autopsy showed the conditions diagnosticated during life to have been correct

DR HAROLD WILLIAMS asked if the autopsy of Dr Stuart's case showed any signs of the chronic abscess from which the boy had suffered some years before?

DR STUART said that there was no internal evidence of any lesion referable to the abscess, no trace of which was found Griffith, however, mentions this as one of the causes of cirrhotic disease of the liver

DR WILLIAMS remarked that in answer to the question "Was the injury the cause of the cirrhosis?" it was conceivable to suppose that the kick might have been the cause of the chronic peritonitis and that the adhesions resulting therefrom might have acted as a cause of the cirrhosis by constricting the blood vessels of the liver Dr Williams asked if the adhesions noticed in this case were found to cause such interference

DR STUART replied that this was not the case That it had been discussed at the autopsy, but that while many adhesions were found, none were in such position as to warrant such a conclusion

(To be concluded)

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, May 4, 1887

THE PRESIDENT, JOS TABER JOHNSON, M D, IN THE CHAIR

(Concluded from page 442)

DR M G ELLZEY read a paper entitled

ANTISEPTICS IN MEDICINE AND SURGERY

(See page 459)

DR A F A KING was very much interested in the subject and had accepted the opinions of the great surgeons As Dr Ellzey had antagonized these beliefs, he (Dr K) would like to know if Dr Ellzey could prove his statements by demonstrations or experiments

DR ELLZEY had not formed his opinions from experiments, but from tables showing the value of the

different antiseptics, and the opinions of eminent chemists and such operators as Keith, Pasteur, Stern berg and others He had not experimented with the different germicides because he had not the facilities

DR KING was not familiar with the results of experiments All lecturers on surgery recommend the 1–40 and 1–20 solutions of carbolic acid, but Dr Ellzey informs us that nothing less than 1–10 solution has germicidal powers Why have not surgeons adopted this strength? Dr Ellzey says that it is impossible to wash the vagina clean with douches We may leave a million microbes, but do we not do some good if we wash out several millions? It may be true that some persons are susceptible to mercuric or carbolic acid poisoning, but that is no reason for abandoning them until we can find something better He agrees with Dr Ellzey in the value of high temperatures as nature's germicide, another proof of his theory of fever being a conservative process for the cure of disease

DR J FORD THOMPSON said this was the fist time that he had ever heard Dr Ellzey on antiseptics, but some time ago he read an article of the doctor's on the same subject in which he took the same ground He agrees with Dr Ellzey in the efficacy of covering the wound with cotton, but he thinks the germs would be kept out better if the cotton was medicated He had recently seen an article by Bantock upon antiseptic surgery, and this system was his rule of practice He was surprised to find that Bantock states that antiseptic surgery has had its day, the practice being so common as to be almost universal Bantock, Keith and Tait are specialists, and their work is almost entirely confined to the abdominal cavity, which, in his opinion, is the least adapted to antiseptics Nor did he believe in weak solutions, which he thought simply lulled our suspicions to rest without being germicidal However, he did not consider the question settled He uses the bichloride solution of strengths varying from 1–1,000 to 1–10,000 There are certain situations on the body to which antiseptics cannot be properly applied, as, for instance, the eye, ear, nose and mouth In these places, after a surgical operation, he considers it impossible to apply a strictly antiseptic dressing He does not believe with the enthusiasts that when antiseptics are used there will be no suppuration A certain amount of suppuration is an almost necessary concomitant of the reparative process and is innocuous

He believes in the prevention of the entrance of bacteria into the wound by an antiseptic dressing Putrescence is what we aim to prevent, and the antiseptic dressing is intended to shut out the germ of it That antisepsis is the greatest God send to surgery has been proved in every amphitheatre In his practice he does not depend wholly upon antiseptic solutions, but uses them as aids Every surgeon has a routine practice which is of more or less consequence to success True, the parts may be washed with turpentine, ether, soap, etc , but that is not antisepsis, as is usually understood Everything about the wound must be aseptic and as far as possible antiseptic—especially the dressings

The dressing is the weak point in Dr Ellzey's theory He substitutes aseptic cotton for aseptic and antiseptic dressings Guérin introduced this into field and hospital practice, but it is not now used Let the doctor take cheese cloth, boil it in soda, wash it and then let it soak in the mercuric solution for weeks Is not this superior to non medicated wool? Many things may be weeded out of antiseptic surgery, but the principle of antisepsis will remain the same, and never be abandoned The incision in the abdominal wall is an ordinary incised wound and will heal without extra dressing, as that class of wounds will in any other situation

DR T C SMITH asked Dr Thompson if the abdominal cavity, the eye, the mouth, etc , were not fields for testing the value of antiseptic surgery, what were?

DR THOMPSON replied that it was impracticable to test it on those special regions It must be applied to surgery in general

---

FOREIGN CORRESPONDENCE

LETTER FROM PARIS

(FROM OUR OWN CORRESPONDENT)

Treatment of Fractures by Massage—Propagation of Typhoid Fever through the Air—Urobilinuria—A New Caustic Paste

At a recent meeting of the Société de Chirurgie of Paris, Dr Lucas Championnière read a report of two cases of fracture treated by massage The one is relative to a fracture of the internal ankle, the other to a fracture of the lower third of the tibia without displacement In the latter case, the patient was able to walk at the end of 25 days To these two cases Dr Championnière adds a third, the report of which he obtained from Dr Lostrine, a surgeon, relative to a fracture of the lower third of both the bones of the leg The patient was completely able to walk on the thirty-fifth day From these cases, Dr Championnière suggests that massage acts here not only in making supple the joints in the neighborhood of the fractures, but also, contrary to what might have been supposed, it favors the formation of the callus, and the explanation offered is that this result proceeds from the massage effecting the resorption of the effused products which interfere with the formation of the callus According to Dr Championnière's experience, it is only the first séance that is painful, but the patient soon gets accustomed to the massage and feels great benefit from it During the operation pressure should be made in the neighborhood of the fracture, but not on the fracture Dr Berger observed that the patient of Dr Championnière who walked on the thirty fifth day after a fracture of the leg, proves nothing in favor of the superiority of this method, as similar results are frequently obtained by the old procedures of treatment Moreover, Dr Berger understands that the method may be serviceable for fractures of the articular extremities of bones, in which there is no great danger

of false joint, but for diaphysitic fractures he understands the utility of massage less, as in such cases one should always fear the formation of false joints Dr Marc Sée stated that he obtained the same results as Dr Lucas Championnière by means of the elastic band He considers this as being a great deal more simple, and, in any case, it never requires the sittings of massage of one hour and a half, which would constitute a serious obstacle to the introduction of this method in practice

Dr Féréol lately read a paper at the Société Médicale des Hôpitaux, in which the author, Dr Devalz, of Eaux Bonnes, intended to show that typhoid fever may be propagated through the air as well as by the fluid or solid substances introduced into the stomach The following illustrative case is given by the author A lady arrived at Eaux Bonnes from Paris with the primary symptoms of typhoid fever, of which she was cured at the end of four weeks Three daughters of the proprietor of the hotel in which the lady was staying, who occupied a room adjoining the privy in which the dejections of the patient were thrown, successively fell ill with the malady The author thinks that he has a right to conclude from this circumstance that in this case, at least, the disease was communicated through the air which circulated freely between the privy and the room occupied by the patients, every precaution having been taken to prevent contamination of the food or drinking-water

At the same meeting Professor Hayem read a very interesting article giving the results of his researches on urobilinuria The author demonstrated how, by the aid of the spectroscope, urobiline may be recognized in the serum of the blood and in the urine In the second part of his work, Professor Hayem devotes some considerations to clinical results According to him, the excretion of an abnormal quantity of urobiline constitutes urobilinuria This phenomenon may be transitory, or it may be intermittent, or it may present itself in a permanent manner When the affection is slight, the color of the urine is scarcely altered, but when well marked, we have the hemapheic urine of Gubler Urobiline is found in the urine, either alone, or associated with a more or less considerable quantity of biliary pigments It is found constantly during the periods of asystolic cardiac affections It is frequently met with in intoxications, diseases of the liver, cerebral affections, and in certain chronic maladies It is also frequently met with in the greater part of acute affections Dr Hayem does not believe that urobiline alone can produce jaundice Finally he had been able to establish, in all the cases in which he observed urobilinuria, a venous stasis of the liver with slight catarrh of the biliary ducts, and with infiltration or fatty degeneration of the hepatic cells In the third part of his paper, Dr Hayem studied the origin of urobiline For the learned Professor, the diseased liver, instead of secreting normal pigments, secretes urobiline, which, according to certain clinical facts, would pass directly from the biliary canalicules into the blood In conclusion, Dr Hayem establishes the prognostic value of the symptom of urobilinuria as follows When temporary it indicates temporary modifications of the hepatic circulation When permanent, it indicates infiltration or the fatty degeneration of the hepatic cells

The powerfully modifying action of caustics has always been considered a precious resource in surgical practice According to the *Courrier Medical* Dr Jules Felix, of Brussels, finding a great number of inconveniences attending the ordinary caustics in use, proposes a paste as a substitute for them The following is the formula of the paste Powdered starch 37 grams, wheat flour 112 grams, bichloride of mercury 1 gram, dried chloride of zinc 110 grams, pure iodol 10 grams, croton chloral 10 grams, bromide of camphor 10 grams, crystallized carbolic acid 10 grams, all to be mixed up in a glass mortar, the ingredients being well pulverized separately, and gradually add to the whole the quantity of distilled water necessary to obtain a homogeneous paste, which keeps in a perfect state of preservation for an indefinite time When required to be used the quantity necessary should be pressed in the hand previously moistened, and the paste could then be pressed into any shape or form The author claims the following advantages for this preparation 1 Pain very supportable and slightly intense, without any general reaction 2 Production of an eschar which is hard and well limited, detaching itself quickly or allowing itself to be easily removed with a sharp instrument or by scraping 3 Marked modifying and antiseptic action 4 Powerful hæmostatic 5 Easy to be manipulated and put into any form according to circumstances 6 This caustic not being fusible, nor deliquescent, may be easily applied to any part, where it may remain more or less long time (from 6 to 24 hours), according to the intensity of action the surgeon may wish to obtain 7 The eschars fall off in a few days, by the application of glycerine with or without carbolic acid A B

DOMESTIC CORRESPONDENCE

SALIVARY FISTULA

In June, 1885, I excised a sebaceous tumor which had been located mostly in the space bounded by the angle of the jaw in front, and the lobe of the ear above The tumor had lain partly over the parotid gland in front of the lobe of the ear I had expected to be able easily to lift the tumor out of its bed after making a free incision, but I found it very tightly bound down and intimately connected by areolar tissue—with the surrounding tissues—making a careful dissection necessary to dislodge it The operation was very bloody and my assistance was indifferent, but the tumor was ultimately dislodged The wound seemed to be healing kindly until one day my patient informed me that at times a gush of fluid flowed from what was a small remnant of the wound I became aware that I had a salivary fistula to contend with I must have wounded the parotid gland with the scalpel in dissecting out the tumor and in removing what was simply a deformity, I had substituted an affliction which

was an active nuisance far more troublesome than the original deformity

Examination showed the existence of a fistulous channel with a diameter of about three sixteenths of an inch, and from this channel the saliva flowed freely whenever food or any sapid substance was taken into the mouth My patient's complaint was temperate though mildly reproachful, and he was solicitous for relief from this new affliction

I kept my patient's mind occupied for a time, in what I knew to be useless efforts to heal the sinus until I might think out an efficient scheme After carefully looking over the methods of Ericson and Bryant I concluded that the use of the cautery in their cases was irrational—and also that the nature of the salivary sinus such as my case afforded data to—which might be fitted a rational method of cure

The healing of a salivary fistula is prevented by the intermittent flow of saliva—which bathes the walls of the sinus, and prevents union When an acute inflammation occurs, in the parenchyma of a gland, the cells affected by this inflammation cease to form their particular secretion until the inflammation becomes resolved Therefore to heal a salivary fistula, it is necessary to induce an acute inflammation in the secreting cells of the gland, and at the same time an adhesive inflammation of the walls of the sinus, that obliteration of the sinus by adhesion may be effected before the cells of the gland resume their proper function—by the abatement of the inflammation affecting them The actual cautery induces such an inflammation as is needed, both in the cells of the gland and in the walls of the sinus, but it does more, it kills what tissue it touches and before union can occur the sloughs must come away, and by this time, the function of the secreting cells is reestablished and the same state of affairs exists as before the use of the cautery

In my case, I filled the sinus completely with fly-blister, and let it remain several hours After removing the fly blister, the sinus was pulled together with adhesive straps This resulted in a partial union of the sinus I next painted the sinus to its bottom with cantharidal collodion and again pulled it together with adhesive straps, and the result was a complete union of the walls of the sinus, and permanent cure of the difficulty, as two years have now elapsed and the channel has not re opened

These remarks apply of course only to such cases as are not complicated with obstructions in the duct proper of the gland and to cases only of traumatism directly to the gland itself

Silverton, Colo , July 16, 1887 J W BROWN, M D

INTUBATION

Dear Sir —I have devised the following improvement on the O'Dwyer intubation set, which entirely obviates the difficulty of properly adjusting the extractor

An eye should be drilled in the anterior or stationary jaw of extractor, about its centre, and from the inner opening a groove cut to the tip of jaw sufficient to accommodate the double thread coming from the tube The thread hole in tube should be drilled about 1 inch from neck of tube, having its external opening countersunk to receive knot on thread Both ends of thread should emerge from upper opening of tube, the obturator being grooved for their reception Now by introducing the free ends of thread into the eye of extractor, the extractor is threaded into the tube with facility and precision

For the application of nitrate silver solutions I suggest the following To one end of a small glass tube attach the bulb of a medicine dropper, to the other a camel's hair pencil, the quill of which is made pervious, or a piece of sponge or cotton may be made to answer for the brush end A U shaped bend should be made near the bulb With this the solution may be applied in any quantity without danger of the disagreeable dripping so common with an ordinary brush Respectfully,

W V MORGAN, M D

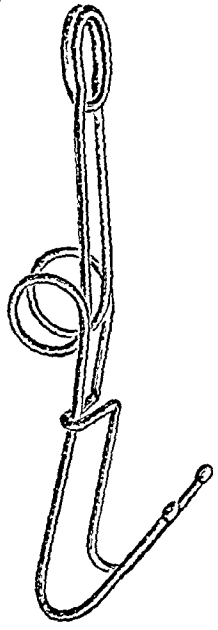
Indianapolis, May 12, 1887

NEW INSTRUMENTS

IMPROVED NASAL SPECULUM

BY I W FINK, M D

HILLSBORO ILL



Necessity is said to be the mother of invention, therefore appears the accompanying cut, representing an instrument brought into existence by me for the examination of the nasal passage—a Nasal Speculum Like many other instruments intended for the same purpose, it has its good qualities as well as its faults

If it is worthy of merit, it is worthy of publication, and the medical profession is entitled to its use

NECROLOGY

J W D OSGOOD, M D

Jonathan Walter Dandola Osgood, M D , of Greenfield, Mass , was born in Gardner July 29, 1802 He was the son of Rev Jonathan Osgood, M D —a graduate of Yale, and for many years the only minister and physician of his town—and Orange Wadsworth, of Farmington, Conn The subject of this notice was graduated at Dartmouth College in 1823

He studied medicine in Philadelphia and Dartmouth, taking his medical degree in 1826 He opened an office in Providence, R I, but remained there only a few months, beginning his practice in Templeton, Mass, in 1827 In 1858 he removed to Greenfield, Mass, where he died May 15, 1885

The son of a man who stood high, both as a clergyman and a physician, Dr Osgood naturally had a deep sense of the dignity of his profession He entered it not for gain nor for a livelihood merely, but as a sphere of beneficent service, alleviating the ills and promoting the welfare of his fellow men, and therefore entitled to the best energies at his command Accordingly he was always an earnest student in both the theory and practice of medicine He entered actively into medical societies being a member of the Worcester District Medical Society, of the Massachusetts Medical Society—of which he was once Vice-President—and also of the American Medical Association since 1853, and pretty constant in his attendance He kept up with the literature of his profession, even in his old age For the acquainting of himself with all lines of progress in his work he frequently visited the hospitals of New York and other large cities As a consequence he was fresh and living in his knowledge, and growing skilful as a practitioner He not only had a large practice in his own community, but was also in wide demand for counsel elsewhere He excelled in diagnosis and was a good surgeon, ever ready in expedients at times of emergency His gifts were exercised in a spirit of such genuine interest in his patients, with such gentleness and faithfulness, that he made himself the trusted and beloved friend, and almost a member, of every family that he served

In his relations to the members of his profession he was the soul of honor, regarding scrupulously their rights, observing with delicacy professional proprieties, and always commanding the respect and confidence of his associates Outside of his profession he had business interests but no business activities, only taking pains to be connected with men whom he could implicitly trust, that he might give his entire attention to the duties of his chosen calling Beyond his profession he read widely, having an intelligent interest in science, biography, and especially history At the time of his birth his father was evidently a reader of history, and had become an admirer of the celebrated *Doge of Venice, Enrico* Dandolo, of illustrious patrician family, who bore glorious part in the Latin conquest of Constantinople, which so changed the face of Europe It was this admiration of a character distinguished in history that conferred upon the subject of this sketch his third name

Dr Osgood was exceedingly happy in the formation and development of his domestic relations, but through the vicissitudes of a long life he was called to drink deep of the cup of domestic sorrow In 1834 he married Eliza, the daughter of General Lewis Barnard, of Worcester, Mass She died in 1835, leaving a son, Walter Barnard In 1838 he married Mima Florella, daughter of Dr James Stone, of Phillipston, Mass Of this marriage there were born three children, James Stone, Eliza Florella, and Caroline Phebe In 1868, after thirty years of domestic felicity, Dr Osgood was called upon to part from the wife who had shared largely in creating as well as enjoying his general prosperity Four years later his older son, Walter Barnard, on whom he had come to lean with confidence and pride, was taken from him Seven years elapsing, in 1879, his younger daughter, to whom he was tenderly devoted, after a protracted and distressing illness, passed from his sight As Dr Osgood had accepted his prosperity with wise soberness, so he endured his afflictions with Christian fortitude One great blessing was accorded unto him to the end, of which he often spoke with devout thankfulness It was the affectionate devotion, the intelligent sympathy, the always adequate helpfulness of the daughter that survives him

Dr Osgood was true to the faith of his Christian parentage He was not a church member, for the creeds with which he was acquainted perplexed him, but he freely avowed his faith in the Lord Jesus Christ as his saviour His last illness was very distressing, the autopsy revealing ossification of the coronary passages of the heart, but his mind was clear and his interest in the important affairs of the time was unabated His bible was a constant companion He was frequently in prayer He endured his sufferings with resignation, and met death with Christian composure S H L

MISCELLANEOUS.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM SEPTEMBER 24, 1887, TO SEPTEMBER 30, 1887

Lt Col A K Smith, Surgeon, granted leave of absence for one month and fourteen days, to take effect upon his being relieved from duty at U S Military Academy S O 223, A G O, September 24, 1887

Capt R W Johnson, Asst Surgeon, granted leave of absence for twenty one days, to be taken advantage of so that he will return to his station at latest by the middle of October, 1887 S O 204, Div Atlantic, September 23, 1887

First Lieut W D Dietz, Asst Surgeon, leave of absence extended one month S O 223, A G O, September 24, 1887

First Lieut Wm L Knudler, Asst Surgeon, ordered to accompany Light Battery "F" Fourth Artillery, from Ft Snelling, Minn, to the International Military Encampment at Chicago, Ill S O 97, Dept Dak, September 20, 1887

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY, DURING THE WEEK ENDING OCTOBER 1 1887

Asst Surgeon V C B Means, ordered for examination preliminary to promotion

P A Surgeon E Z Derr, detached from Navy Yard, New York, and to the "Nipsic"

P A Surgeon Richard Ashbridge, detached from Naval Academy, Annapolis, Md, and wait orders

P A Surgeon A H Russell, ordered to the Naval Academy, Annapolis, Md

P A Surgeon C G Herndon, detached from Naval Dispensary, Washington, D C, and to the 'Enterprise"

P A Surgeon Geo Arthur, detached from the Museum of Hygiene, Washington, D C, and to the Naval Dispensary

P A Surgeon S H Griffiths, ordered to the Museum of Hygiene, Washington, D C

Medical Inspector J C Spear, leave of absence granted until July 1, 1888, with permission to leave the United States

ORIGINAL ARTICLES

ABSTRACT OF A PRELIMINARY REPORT OF EXPERIMENTAL RESEARCHES CONCERNING THE INFECTIOUS NATURE OF TRAUMATIC TETANUS

Read in the Section of Pathology of the Ninth International Medical Congress, September 6, 1887

BY EDWARD O SHAKESPEARE, A M, M D,

OF PHILADELPHIA

PATHOLOGIST TO THE PHILADELPHIA HOSPITAL, ETC

The author reported in detail a long series of experiments which are still in progress, and announced the results already obtained Upwards of fifty inoculations have already been made Two methods of inoculation have been employed—intra cranial inoculations after the method of Pasteur in the case of rabies, and subcutaneous or inter-muscular injections by means of hypodermic syringes The inoculations and injections were made with aseptic precautions, and with sterilized instruments In none of the experiments was there any sign of accidental infection, such as suppuration, etc The material used for inoculation was in general obtained from the medulla or the spinal cord, and by culture in neutral or slightly alkaline flesh glycerine agar as recommended by Roux for the culture of tubercle bacilli The tetanus material was taken, under aseptic precautions, from a horse and a mule dead of traumatic tetanus in the Veterinary Department of the University of Pennsylvania, the brain, medulla and cord being removed one and three hours respectively post mortem and immediately kept on ice until used The inoculation material was in general prepared in the following manner A small piece of the medulla or cord was thoroughly rubbed up in sterilized distilled water, after the solid particles were allowed for a few minutes to subside to the bottom of the vessel, the opalescent emulsion thus obtained was drawn off by means of sterilized pipettes, and placed in small sterilized vials until used, never having been thus kept longer than three hours before inoculation Eight control experiments were made, and none of these rabbits became ill The author concludes his paper as follows

Resume of results

First Series—Eight rabbits were inoculated sub dura cerebri from the medulla of a horse dead of tetanus, between August 1 and 18 inclusive The rabbit inoculated directly from this horse showed the first symptoms of tetanus within 15 hours and died of well marked tetanus within 48 hours after inoculation Both the period of incubation and that of death became markedly shortened in continuing the inoculations from rabbit to rabbit

Second Series—Four rabbits were inoculated sub dura cerebri from the same medulla of horse The rabbit inoculated directly from the horse showed the first symptoms of tetanus within 20 hours, and died within 48 hours after inoculation Continuing the inoculation from rabbit to rabbit, the period of incubation and of death became markedly shortened

Third Series—Four rabbits were inoculated sub dura cerebri from the same medulla of horse after it had been kept on ice a day longer The rabbit inoculated directly from the horse showed the first symptoms of tetanus within 24 hours and died within 48 hours after inoculation Continuing the inoculations from rabbit to rabbit, the period of incubation and of death became markedly shortened

Fourth Series—Three rabbits were inoculated sub dura cerebri from the medulla of a mule dead of tetanus, with the same results as in the preceding series

Fifth Series—Seven rabbits were inoculated under the skin and into the muscular tissue of the back, from the medulla of the horse above mentioned One died within 18 hours and another died within 10 days, but neither of them showed any signs of tetanus A rabbit inoculated sub dura cerebri from the medulla of the latter on August 15, is still living and well on September 4, date of the last observation

Sixth Series—A rabbit, which had been inoculated under the skin directly from the horse on August 1 was 8 days afterward inoculated sub dura cerebri from the medulla of the last rabbit of the third series It became sick and died promptly of tetanus within the shortened period, a rabbit inoculated sub dura cerebri from its medulla, showed signs of tetanus within 20 hours, but did not die until 5 days after inoculation

Seventh Series—Six rabbits were inoculated sub-dura cerebri from emulsions of spinal cords of rabbits, which had died of tetanus within the shortened period above mentioned These cords had been treated in a manner similar to that employed by Pasteur for the attenuation of the virus of hydrophobia, during periods varying from 3 to 15 days Five of them died of marked tetanus, the symptoms appearing and death occurring within periods longer than those of the corresponding rabbits from which the

medulla had been taken, and usually proportional to the length of time the cord had been drying. One of the six showed doubtful symptoms, but nevertheless very promptly died

Eighth Series —A rabbit was inoculated sub dura cerebri from the medulla of a rabbit which had died after inoculation from the cord which had been 15 days drying It showed the first signs of tetanus in 40 hours and it died of tetanus 7 days after inoculation A rabbit was inoculated sub dura cerebri from the cord which had been drying 14 days, and it died of tetanus in 20 hours A rabbit and a cow were inoculated sub dura cerebri from its medulla The former quickly died of marked tetanus The latter died within 2 days without marked symptoms, and from the autopsy it seemed probable that injury to the brain had been the cause of death (there had been great difficulty in performing the operation of inoculation) A young rabbit inoculated sub dura cerebri from this cow's medulla died within 10 hours, but showed no signs of tetanus, and another rabbit inoculated sub dura cerebri from the medulla of this rabbit August 27, is still living and quite well September 4, never having shown any signs of illness

Ninth Series —Three rabbits were inoculated sub-dura cerebri September 1, from spinal cords of tetanus which had been drying respectively 23, 27 and 28 days (these cords were the same as those which had been drying longest, mentioned in the preceding seventh series) The rabbits inoculated from the 23 and 28 day cords showed no signs of illness up to the time of the last observation, September 4 The one inoculated with the 27 day cord for the first time showed stiff jaws and difficulty in eating on the afternoon of September 4

Tenth Series —Three rabbits which had been inoculated under the skin on August 18, and had remained perfectly well, were inoculated sub dura cerebri September 1, from the same cords mentioned in the ninth series The rabbit inoculated with the 23 day cord was found dead the next day, but it showed no signs of tetanus either externally or at the autopsy That of the 28 day cord showed stiff jaws and would not eat for the first time on the afternoon of September 4 That of the 27 day cord showed no signs of illness up to the last observation, September 4

Eleventh Series —Three rabbits were inoculated sub dura cerebri, August 31, from cultures started from the horse's brain August 1, and renewed once, viz , on August 20 One of them has remained quite well up to the last observation, September 4 One remained quite well until September 2, afternoon, when it showed intermittent trismus and indisposition to eat This condition continued up to date of last observation, September 4 One showed slight signs of tetanus for the first time September 3, and had them also up to date of last observation, September 4

Twelfth Series —A trial attempt was kindly made for me by Dr L Wolf, Demonstrator of Medical Chemistry in the Jefferson Medical College, to isolate a ptomaine from the brain, medulla and cord of the mule and cow above mentioned The Stass-Otto method was more or less closely followed

The product obtained from the mule was injected under the skin of the back of two rabbits They became very ill within 20 minutes, being slightly paralyzed and exceedingly restless, frequently getting down flat on the belly and up again and jerking the hind legs up, but they showed no marked convulsive movement or trismus They entirely recovered within 6 hours

The product obtained from the cow produced but little and only very transient and indefinite effects

Note —Several autopsies of the tetanic animals were made, and they invariably showed intense congestion of the lungs, trachea and kidneys Sometimes there was congestion, oftentimes none at all, of the central cerebro spinal nervous system The mucous membrane of the stomach was apparently normal

Conclusions drawn from the author's personal researches

1 Traumatic tetanus of the horse and mule is, at least sometimes if not always, an infectious disease, transmitable to other animals and therefore possibly also to man, and during the progress of this disease a virus is elaborated and multiplied which is capable of producing the same infectious disease in some other animals when placed beneath the dura mater of the cerebrum

2 This virus is contained in the medulla and spinal marrow of the animal suffering with the disease It is like the virus of hydrophobia, capable of being strengthened in virulency by inoculation sub dura cerebri from rabbit to rabbit, and, like the virus of hydrophobia, is capable of attenuation by exposure for a sufficient time to the action of dry air at a temperature of Summer heat and, still again like the rabic virus, its effects are far more intense when the virus is inserted beneath the dura mater cerebri than when injected beneath the skin or between the muscles of the back

3 The author reserves his conclusion concerning a prophylactic effect of inoculation of the attenuated virus, until the completion of experiments which are at present in progress

Conclusions drawn from the author's experience which correlated with those of Nicolayer, Carle and Ratone, Rosenbach, Ferrari, Flugge, Hochsinger, et al

Traumatic tetanus of the lower animals and of men, at least sometimes, possibly always, is a specific infectious disease due to the action of a specific infectious virus which exists in the tissues at the seat of infection, in the blood and in the central cerebro-spinal nervous system

In view of the experimental evidence which we possess at present and of numerous unassailable observations of many surgeons and veterinarians, there seems to be ample warrant for the admission that not infrequently tetanus in man is acquired directly and indirectly from some of the domestic animals which surround him, notably the horse

INFANT FEEDING, ESPECIALLY WITH REFERENCE TO SUBJECTS WITH INFANTILE ECZEMA

Read in the Section on Diseases of Children, at the Thirty Eighth Annual Meeting of the American Medical Association June, 1887

BY L DUNCAN BULKLEY, A M , M D ,
PHYSICIAN TO THE NEW YORK SKIN AND CANCER HOSPITAL, ETC

In the following simple and practical paper I do not intend or expect to present any very new or startling points in regard to the subject under consideration, nor have I any special food to advocate, and not even any single fixed method of feeding to propose or defend I confess myself to be still a searcher after the best nourishment for, or rather after the best method of nourishing, the growing child, and especially one afflicted with infantile eczema I have studied the subject many years, in hundreds or even thousands of cases, but believe that much may yet be learned, and that we by no means appreciate the greatness of the subject sufficiently, and feel certain that the majority of practitioners do not give it the attention it deserves, while I am perfectly sure that the laity are by no means aware of the importance of proper feeding, nor rightly acquainted with the principles involved Certain am I, from experience, that the right principles are often most egregiously violated, even by those of more than ordinary intelligence, while among the poor the ignorance and neglect of the matter is often appalling

The present paper grew out of a discussion bearing upon "Infant Feeding" in the Children's Section of this Association at its meeting at New Orleans, two years ago, when, by vote of the Section, the writer was asked to prepare and present a paper on the subject.

In attempting to fulfil this request I shall not tax your time and patience with any scientific study of the processes of digestion, nor shall I attempt any discussion of the various foods which are more or less favorably known, neither shall I enter the literature of the subject The object of the paper is rather to introduce the topic for discussion, and to present the practical aspect of the case as it has developed itself in my observation clinically

If we look in the text books, either on Diseases of the Skin or on Diseases of Children, we find but little reference to the matter of diet in children with eczema, and only the most general directions given Indeed, one of the best writers on Diseases of Children, Eustace Smith, says "Too much importance, however, need not be attached to the subject of diet in the treatment of eczema " Now, while all agree that *too* much importance must not be attached to the element of diet, in the management of infantile eczema, experience has shown me most conclusively that in by far the larger share of cases far *too little* consideration is given to the subject, and that judicious directions in regard to the matter have not only aided greatly in curing a present attack, but have also sufficed to prevent its recurrence

Much that will be said in connection with this subject is undoubtedly well known to my hearers, indeed, much of it is no doubt self-evident to an intelligent observer, but I feel it necessary to treat the subject fully and plainly, because, however intelligent parents and nurses may be in other matters, it seems impossible for them, ofttimes, to exercise the slightest common sense or judgment when it comes to the matter of what shall enter the infant's mouth Much that will be said in regard to those affected with eczema applies equally well to infants with other diseases, or, indeed, to those in supposed health, but is none the less necessary and important in the present connection

I find that it is almost useless to simply direct the attendants on infants that the diet shall be plain and nutritious, or to say that the diet must be restricted, or that the infant requires more nourishing food In the majority of cases this really means nothing, either on account of the ignorance or carelessness of the mother or nurse, often they may desire most earnestly to aid the physician, but, having no knowledge of the physiological processes of digestion, or of the relative value of foods, or indeed, of the end to be accomplished, and being generally guided by the advice of the persons with whom they come in contact, nurses and others, it often results that they are about as far from right as it is possible to be, unless particularly instructed by the medical attendant

In dealing with a case, therefore, it is necessary to give both negative and positive instructions, to define clearly both what and how the child shall *not* eat and drink, and how the feeding shall be carried on—in many cases the former is even more important than the latter

I do not wish to offend my audience by the very simple and homely matters presented, but I have seen, both among the poor and even among those in the higher walks of life, such gross errors in regard to either what was given to children or what they were allowed to have, that I cannot forbear mentioning some of the articles in this connection I have seen even very young infants with candy, even of the worst kinds, cakes of all varieties, cheese, apples, oranges, bananas and other fruits Recently a babe 6 months old, covered with eczema, was brought to me, biting lustily on and having eaten half of an orange, devouring the skin and all Once I found a pickle in an infant's hand, while it is most common to see crackers, even of the most indigestible varieties, given to infants, "just to keep them still," as the mother will say Careful inquiry will elicit the fact in a considerable proportion of cases of infantile eczema, that the little patients get more or less tea and coffee, the attendant often saying that the infant is exceedingly fond of tea, while occasionally have I found that they were also given beer

It is not at all uncommon, in going carefully over the history of infants with eczema, to find that the patient is accustomed, even during the first year of its life, often when but a few months old, to take some of the food of adults, eating, as the mother will say, a taste of everything on the table, and when closely questioned it will sometimes be found that this may include even pies, and the most indigestible articles So commonly have I found this to be the case that I now always investigate the matter, and

frequently I have refused to treat the patient unless a promise is given that the child shall not come into the room while the food of the family is on the table

While these gross errors in infant feeding are, of course, much more common among the poorer and more ignorant classes seen in dispensaries and hospitals, they also occur in the better classes, even in those where it would be least expected, as I have observed time and again And even at the risk of being thought unnecessarily minute and perhaps commonplace in my treatment of the subject, I must emphasize the fact that, for the thoroughly successful management of infants with eczema, the diet must be most carefully investigated and watched, so that the physician shall be sure that the little patient takes only the articles directed

It would hardly seem necessary to mention such a matter as regularity of feeding But unless this is attended to errors may occur, and I have frequently seen infants where too frequent nursing seemed to be an element in keeping up the digestive disorder which was at the bottom of the eczema, the child is too often given the breast each time it cries on account of the itching of the eruption, and thus the disease aids in perpetuating itself I have also often seen bread, if not a more harmful article, given for the same purpose Efficient local treatment which allays the irritation may, therefore, have more than a purely local action, when it allows the infant to sleep without the constant application to the breast

Having now made certain that the infant will receive nothing but the nourishment intended, it is necessary for the physician to give particular and specific directions in regard to this latter, and often to inquire most carefully into the matter, in order that there may be a perfect understanding in regard to every detail of nourishment

Even when the infant is nursing there may often be some necessity of care and attention As already mentioned, the breast should not be given too often, nor too seldom, nor at irregular intervals The child may also undoubtedly be affected by the condition of the mother, and by what she eats and drinks Often a case of eczema will be benefited by improving the health of the mother in many respects, for frequently eczema is dependent upon poor nourment, and the anæmic, dyspeptic, constipated mother cannot furnish perfect milk I almost always give a bitter tonic with acetate of potassium to a nursing mother with an eczematous child, and am very careful in regard to the condition of the mother's bowels Other mothers need iron, hypophosphites, malt, or cod liver oil, while very frequently it is necessary to give careful attention to the diet of the mother

Many nursing mothers are in the habit of taking large quantities of tea, others take beer, or chocolate, with the idea of aiding in the secretion of milk All of these I believe to be more or less injurious to the nursing infant with eczema, and are forbidden If properly taken, milk affords the best means from which the human milk can be secreted, and there are few who cannot take it with benefit, both to themselves and their nursing infants, if due care be exercised in its administration

The first point which I emphasize is that the milk should never be taken at the meals, nor in connection with any other substance whatever, nor when the stomach contains any food, or remains of food It is best taken pure and alone, as a drink, and preferably at the temperature of the body, never iced, when the stomach is empty, presumably about three hours after a light meal, and four hours or more after a more hearty meal Thus, my constant direction is that nursing mothers should take milk, say about an hour before each meal, and then also during the night if awake, beginning not earlier than about 11 o'clock A quart or two of milk can thus be taken with comparative ease, and its effects appear in the mother and child often in a very striking manner If the milk seems to sour at all on the stomach I frequently have a few drops of liquor potassæ, 10 or 15, or a little bicarbonate of soda, added to each tumblerful

The idea of giving the milk thus on an empty stomach is that it may enter the system, if possible, without passing through the process of curdling and digesting in the stomach When given during the interval and after stomach digestion is finished, the supposition is that the alkaline milk, received into the stomach when this is slightly alkaline, as it is at this time, enters the absorbents at once and mingles with the blood current, as we know it can when injected into a vein It is to be remembered that under the microscope milk globules and those of chyle are hardly distinguishable, and as the blood current is alkaline there is no reason why milk taken in this manner, and entering the lacteals undigested, may not mingle at once with the mass of blood, as does the chyle and as does also the milk when administered in transfusion The addition of an alkali renders this more easy and certain, and when the stomach and mouth seem acid, a little alkali taken in water, quarter of an hour before the milk, serves to counteract this acidity, and prevents the milk from becoming curdled by any remaining acid

The reason of abstaining from food in connection with milk is found in the fact that the gastric juice necessary for the digestion of even the smallest amount of substance other than the milk would curdle the milk, thus requiring a complete digestion of the entire quantity

The proof of the theory that there is some special mode in which milk acts when taken thus alone on an empty stomach, and with the assistance of an alkali when necessary, is found in the clinical experience which has attended a large number of cases in whom this plan has been practiced Many patients who before had been unable to take milk, because it excited in them the so called "bilious" condition, find that they can take it not only with impunity in this way, but with the greatest benefit Another proof is found in the feelings experienced shortly after thus drinking milk, which is often described as one of not only immediate refreshment, but even of exhilaration, which has been likened to that of taking liquor, and many patients, both nursing mothers and others, have repeatedly expressed to me their satisfaction at the success of what seemed to them at first a doubtful experiment

I trust this somewhat lengthy digression will be pardoned, as in reality it has a very decided bearing upon the subject under discussion, because, I believe that by this means of taking milk many infants can be well nourished on the breast alone who otherwise would either be poorly nourished by it, or would have other food given as supplemental, which would certainly not be as efficient as a full supply of healthy breast milk, such as has been provided by nature for the purpose

In the case of small infants with eczema where breast milk is not obtainable, there is a wide field for discussion in regard to the best mode of nourishment, which can hardly be touched upon within the limits of this paper All are more or less familiar with the various artificial foods which have been presented to the profession, and which have each received their advocates, and undoubtedly have each their merits Among the most prominent of these may be mentioned Mellin's, Horlick's, Nestle's, Ridge's, Carnrick's, Savory and Moore's, and what is known as lactated food, each of these and others are claimed by their proprietors as offering the most perfect solution of this most difficult problem, as to what is the best nourishment for the infant deprived of its normal supply—and yet the experience of all must have answered that as yet no perfect substitute has been found, and that indeed there probably never can be found any substance other than mother's milk which will suit every case

Undoubtedly the substance most like human milk is that from animals, and I have to declare my decided preference to this Nature's substitute above all those which have been artificially prepared with a view to represent, or to efficiently take the place of, milk from the human breast, and I have further to express my conviction that many more infants can take and thrive on cow's milk, when properly administered, than is commonly supposed, and my belief that these prepared foods are substituted for milk very frequently to the great disadvantage of the child

I will not occupy time in entering here into details which are familiar to all in regard to the preparation of milk for infants of different ages and conditions Suffice it to say, that special directions should be given in all cases where there is evidence of poor nourishment, and especially where eczema is present

As is well known, cow's milk does not represent human milk exactly, and often requires treatment to suit individual cases, different ages, etc The large proportion of casein in it often renders it difficult of assimilation, and commonly it will require dilution for younger children, while the proportion of fatty matter can be conveniently increased by using the upper third of milk which has stood 2 to 4 hours, a little sugar of milk and salt being added to bring up these ingredients to the proportion found in human milk It is hardly necessary to discuss further details in this direction, thus much is mentioned merely to qualify the claim that cow's milk is of universal service for young infants In some cases cow's milk can only be tolerated when it has undergone the process known as peptonizing, when it will then seem to afford the most perfect nourishment desired

In young infants with eczema, where the nourishment seems defective the greatest gain may sometimes be had from the addition of the yolk of an egg to the dietary This may be given once daily, either raw, or lightly cooked, as poached or boiled, either alone or in connection with other food, the white of egg is not desirable, and should not be given Cream also is often called for, and these will often be found to more than take the place of cod liver oil, which, however, is likewise most serviceable in many cases of strumous habit

I have not mentioned the use of barley-water in connection with the administration of milk because personally I am not in the habit of ordering it much, although it is recommended on high authority and is widely employed In certain cases it acts well in the way of preventing the formation of too solid a curd, and undoubtedly the small amount of nutriment furnished by the barley may be of value Gum arabic water will sometimes prove of service when added to milk, and possibly acts in the same manner

I will not dwell upon the subject of the use of condensed and preserved milk, except to record my approval of them commonly in preference to many of the prepared foods such as have been already alluded to While fresh milk is to be preferred where accessible, there are many occasions where these preparations of consolidated milk serve the purpose admirably well when properly diluted, and at times will seem to suit particular cases even better than fresh milk

I wish to call attention to the value of wheat products as an element in the nutrition of infants with eczema, as well as in those of older years Even quite young infants will be benefited greatly by the addition of crushed wheat to to their dietary, prepared as follows The wheat is well boiled, and then left to stand all night, and again boiled thoroughly in the morning, the second time It is then put in a fine sieve and water added to it, and it is rubbed until most of it passes through, leaving the hard and husky parts behind This may then be given in a fluid state, either mixed with water, sweetened and salted, or with milk, or it may be eaten as a mush In this manner the nutrient portion of the wheat is dissolved by the repeated cooking, and the phosphates and gluten are extracted with the starch, all in a very assimilable form, and are separated from the harder, indigestible portions, which often pass undigested and may do harm Wheat given in this way furnishes, I believe, about the most perfect nourishment for the growing child, and with milk supplies all that can be desired It is slightly laxative, and I have seen many cases of constipation overcome by its use

Coming to older children, that is those between 1 and 3 years of age, when the teeth are pretty well out, it is often most difficult to regulate the diet in such a way that it shall minister to health or recovery from sickness, and it will often require the greatest watchfulness on the part of the physician to prevent the little eczema patient from being made worse by dietary indiscretions The cereals should be given in increasing proportion, preference being given to

preparations of wheat, rather than oat-meal, which will frequently be observed to increase an eruption Bread made from whole wheat flour should be encouraged, eaten with plenty of butter, which improves these cases, especially if they are under an alkali medication Meat juice may also be given in moderation, but care should be exercised that it is not taken in excess, as there is danger of over stimulation, and I have repeatedly seen bad results from excessive use of beef-tea and animal food in these cases

As the teeth are formed the diet must of course be more varied and more freedom must be given, and parents will often think children ill-nourished if they are not allowed a great variety, indeed if they do not take the food of adults But the prodigious mortality from bowel troubles among children under 5 years of age reminds us that much knowledge is yet needed before those having the care of the young shall rightly attend to the diet If life can be thus endangered, the same or other errors in lesser degree must affect the state of the child both in health and disease

I will not take time to discuss more fully our interesting subject, or to enter upon more details in regard to the many possible matters in regard to diet which might be spoken of—they could readily fill a large book Enough has been said to introduce the topic for discussion and to present the points which experience has shown me to be of importance in connection with our subject, briefly mentioned these are as follows

1 The necessity of carefully watching the diet of infants with eczema, and giving special instructions that harmful articles may be avoided

2 Specific instructions in regard to food and its preparation for these cases

3 The more free use of milk, both for nursing mothers and for infants deprived of breast milk

4 The taking of milk by adults apart from all other food in the interval before meals, when an alkaline state of the stomach facilitates its immediate absorption

5 The more free employment of wheat products in the nourishment of older children with infantile eczema

---

SCIENTIFIC COLLECTIVE INVESTIGATION OF DISEASE

Read in Section on State Medicine, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY HENRY B BAKER, M D,

OF LANSING, MICHIGAN

The purpose of this paper is to suggest how "collective investigation of disease" may be put upon a more scientific basis than is usually attempted, to urge the importance of such scientific investigations, and to point out how they may be equitably maintained, through the cooperation of physicians and governments A few illustrations of what has already been accomplished will also be mentioned

The term "Collective Investigation of Disease" has been employed by the British Medical Association to designate a method of investigation inaugurated by that Association in 1881, but urged by Dr Arthur Ransom in a paper before that Association in 1864 The movement was favored by Professor Humphry, Sir William Gull, Sir James Paget and others Referring to the first number of the "Collective Investigation Record," Dr William Roberts said "No one can read it attentively without acquiring a feeling almost amounting to a conviction that the movement is one of real importance, and that it will result in a large addition to our knowledge that could not have been got in any other way[1]" Mr Jonathan Hutchinson, has said "Permit me to say then, that I cannot for a moment doubt that our distinguished associate, Professor Humphry, when he persuaded our Association to organize the large scheme which we are here this afternoon to promote, has done that which will prove of great and lasting advantage to medical and surgical science It is a scheme which deserves from us all the best help that we can give it[2]"

It is usually claimed that one of the chief objects for which medical societies are organized is the promotion and advancement of the medical sciences The building up of an exact medical science cannot go on, with the greatest success, except through the collection of vast numbers of facts bearing upon each of the numerous questions involved, *and the union of those facts by methods which will admit of numerical expression* General laws are reached only through such measures Detailed histories of "interesting cases" of rare diseases, like the beautiful flowers along the pathway of the professional botanist, may serve as agreeable intellectual or emotional stimuli, but for the upbuilding of the medical sciences, we need the systematic collection and comparison of the most ordinary facts, and I think we must all agree with the Editor of the *British Medical Journal* when he says "The chief aim of collective investigation, as applied to the main body of the profession, should be to collect simple everyday facts that can be easily observed and recorded, and which are of value only from their number, and not from the importance of individual observations[3]"

There would seem to be no question that those diseases which are most common are the diseases which it is of most importance to study, for the purpose of learning their causes and how they may be prevented, avoided or treated This being granted, it is proper to inquire whether the medical profession should not ask the cooperation of the *whole people* in promoting those medical sciences which tend directly to the amelioration of the physical condition of mankind Leaving out of the question the subject of the *treatment* of disease, and confining it strictly to the subjects of the causation and best means of prevention of sickness, it would seem evident that the people as a whole should have much greater interests than the physicians have, and

[1] Brit Med Jour, Nov 3, 1883, p 860,
[2] Brit Med Jour, Nov 3, 1883 p 862
[3] Brit. Med Jour, July 7, 1883, p 20

should, not only cooperate, but should supply the greater portion of the pecuniary means for such investigations To a limited extent this is now done in one State (Michigan), and in my opinion the best interests of all will be subserved when it is done in every State in the Union, and by all Governments throughout the civilized world

How can this be done? Perhaps as suggestive an answer as I can give will be to state how one line of such investigation *is* done in Michigan In Michigan the State Board of Health supplies to physicians in different parts of the State printed blanks on postal cards addressed to the office of the Board The blanks contain a list of the most common and most important diseases After the close of each week each observer fills out and sends to the central office a report of the sickness under his own observation as a practitioner The investigation thus far has been limited to the question of the presence or prevalence of each of the important diseases, and it is so planned and compiled as to give this information quantitatively by months (It would give it by weeks if sufficient work were put into the compilation to make it show for weeks instead of by months)

The times of greatest and of least prevalence of each disease being learned in this manner, a similar method of investigation relative to the principal meteorological conditions which prevail is carried on by means of observers in different parts of the State, who take and record tri-daily observations, and report them to the office of the State Board of Health Tables are constructed showing the relations of each important disease to each of the important meteorological conditions, and diagrams accurately drawn to scale still more plainly show what those relations are For instance, I show you a diagram exhibiting by months the relations which sickness from pneumonia bears to the atmospheric temperature, the diagram giving the averages of over 150,000 observations of the temperature, and of over 30,000 weekly reports by physicians Of that which was contributed by the physicians who took part in this investigation, that which has been *used* from the report each week, was the fact whether the physician did or did not see a case of the disease in question The State Board of Health supplied the blanks, the postage, and the compilation of the whole in connection with the meteorological data similarly collected and compiled The results when published are sent to each observer, but they are published as the common property of the world It seems that by this method we are able to learn the times of greatest and of least danger from each important disease, soon we should be able to see exactly what relation each meteorological condition bears to each important disease If these investigations shall be carried on in different States and countries, we ought soon to be able to learn whether the meteorological conditions bear the same relations in all countries, or whether local conditions modify the results, and how they are modified It may be practicable to extend the scope of such investigations by governmental cooperation But at any rate, such cooperation as is now in force in Michigan, will make it possible for medical associations to direct *their* energies to investigations into results of different modes of treatment of diseases, and in therapeutic and other directions so as to supplement those investigations, as to causes and prevention, which it is manifestly the duty of Governments to maintain

PROMPT REPORTS NEEDED

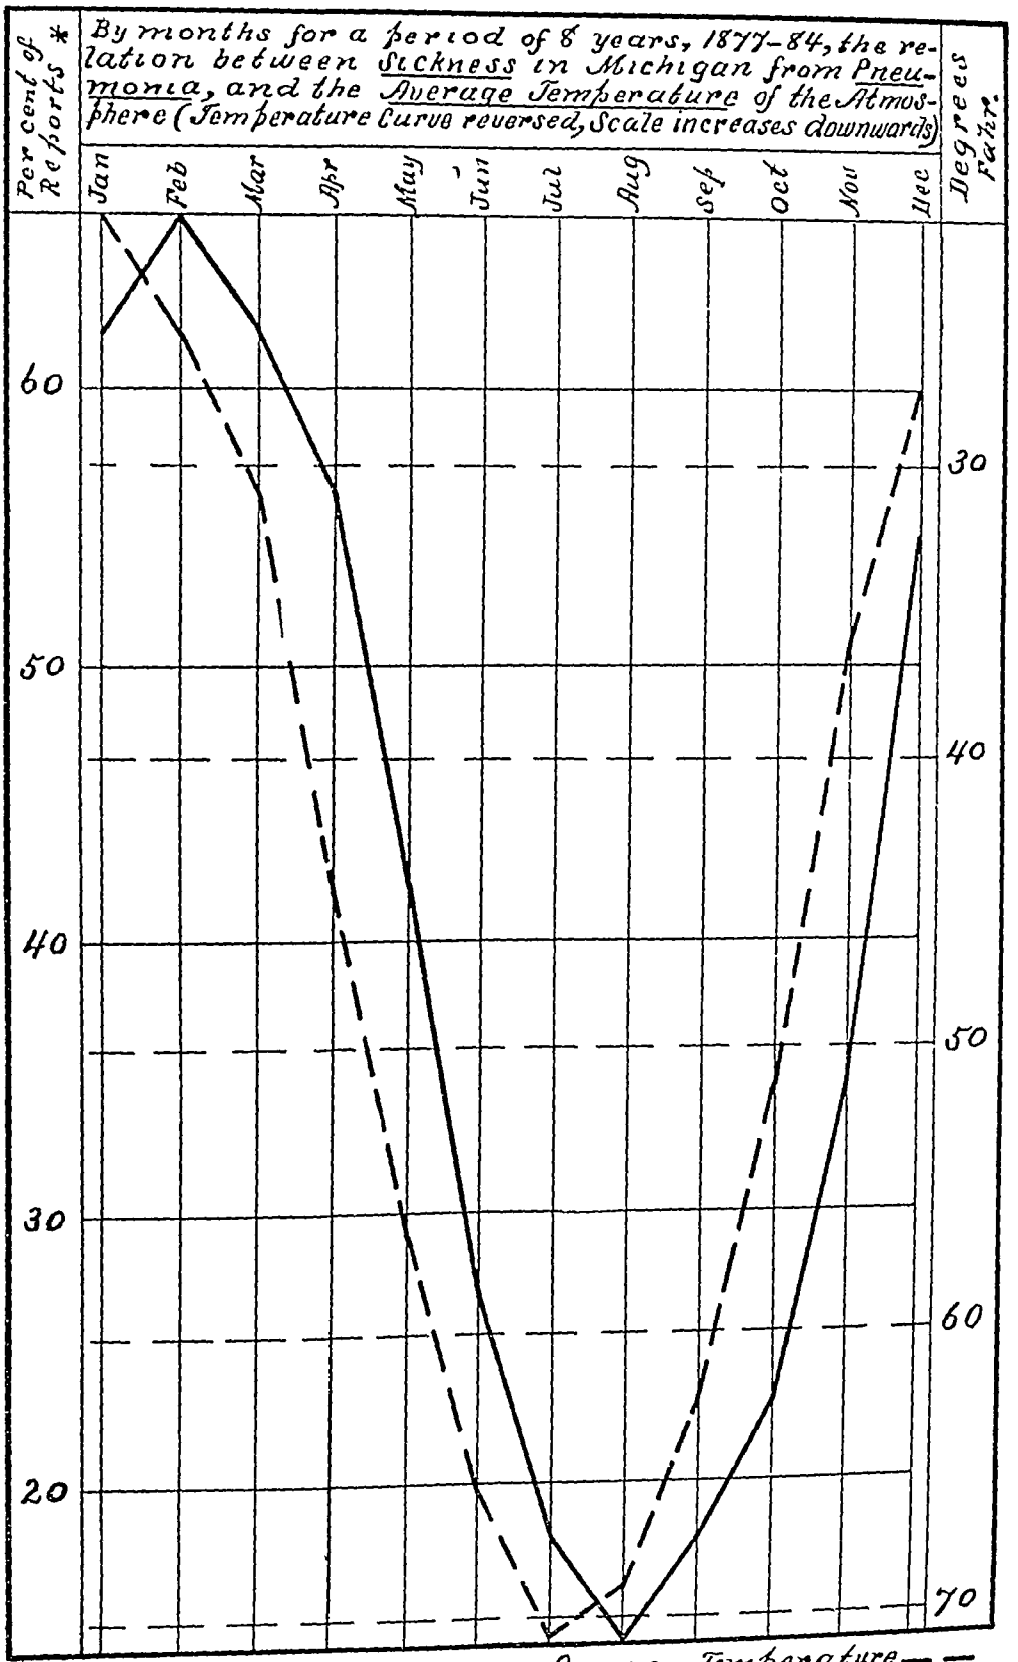
For the most accurate recording of *facts* which shall serve as the basis for the scientific investigation of disease, it is important that the record be made as near as possible to the time of occurrence of the phenomena recorded Otherwise the record is likely to be molded in the direction of preconceived views held by the recorder, because his attention will be attracted to certain phenomena, and he will lose sight of, or sooner forget certain other phenomena. In Michigan it took several years to learn how *much* better weekly reports are than annual reports, for the purpose of studying the prevalence of any given disease In April, 1876, the Michigan Board of Health issued a circular (somewhat like those since used by the Collective Investigation Committee) relative to scarlet fever, and collected facts of value, some of them relating to observations through many years, but on some points more precise information was desired For several years a circular was issued at the close of every year, asking for facts which had been observed during the year just passed But this method also was open to the objections which have been suggested

In September, 1876, the Michigan Board of Health inaugurated a system of weekly reports of sickness, copying somewhat after the plan which for a single year was followed in Massachusetts [1] At first the plan (in Michigan) was defective in that the reports were designed to give the observers best knowledge and belief relative to the sickness in his vicinity, and he was not directed to confine his reports strictly to the cases under his own observation There was then an idea that a great proportion of the sickness in a locality might be reported with approximate accuracy by one of the several physicians in that locality The present plan is based upon the belief that an accurate report of just what was seen by the reporter supplies much more useful facts for scientific study, and that an average practitioner in active general practice, will "in the long run," see an average of the cases of diseases which most frequently occur The present plan supplies the facts, and they are reported within a week after their occurrence It seems to me that this is Scientific Collective Investigation of Disease, and that it is an important work which should be entered upon by all State Boards of Health, and by a National Board of Health, and that physicians should seek to cooperate so far as practicable in such investigations

SICKNESS REPORTS AS SANITARY NEWS

I respectfully submit that the weekly or monthly records of deaths, which are now usually published

[1] I believe that a similar system was carried on in England for a short time about the year 1857 and that an unsuccessful effort to have the Government adopt and pay for its continuance was followed by its abandonment as too expensive for private enterprise by the physicians who had perfected it

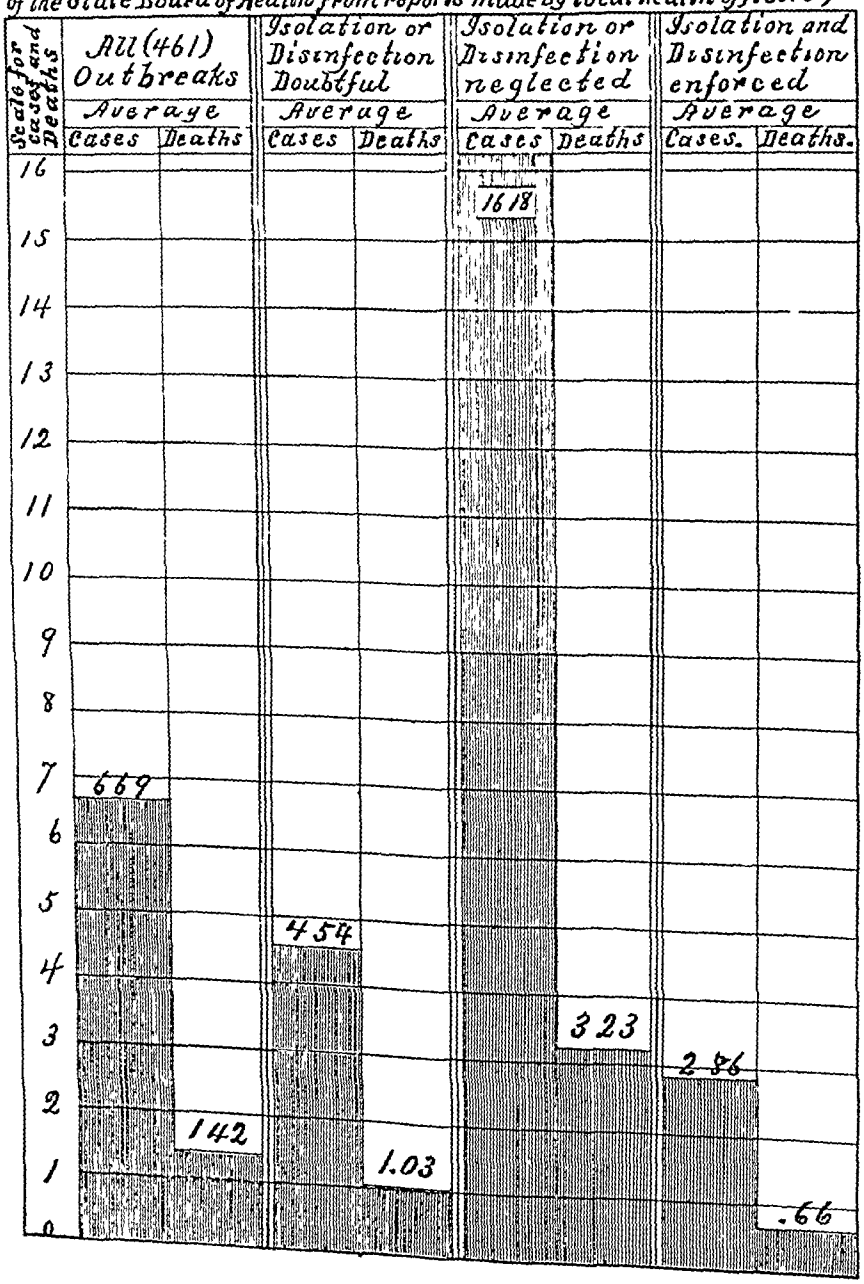


Sickness from Pneumonia ———. Average Temperature — —

*Indicating what per cent of all reports received, stated the presence of pneumonia then under the observation of the physicians reporting.

Over 30,000 weekly reports of sickness, and over 150,000 observations of the atmospheric temperature are represented in this diagram.

Diphtheria in Michigan in 1886, exhibiting the Average Numbers of Cases and Deaths per outbreak - (1) in All the 461 outbreaks Reported, (2) in the 243 outbreaks in which it is Doubtful whether or not Disinfection or Isolation were secured, (3) in the 102 outbreaks in which Isolation or Disinfection or both were neglected, and (4) in the 116 outbreaks in which Isolation and Disinfection were both enforced (Compiled in the office of the Secretary of the State Board of Health from reports made by local health officers)



by boards of health as items of sanitary news, might well be displaced or supplemented by statements of the average sickness which has been observed during the week or month, as the case may be, and reported on this plan of collective investigation There are two good reasons why it should be done

1 There are diseases, which cause much sickness and consequent suffering and expense, which are not correspondingly represented in the mortality statistics I think this may be appreciated by a study of the bulletin of sickness in Michigan in the month of May, 1887, a copy of which I submit herewith, and from which it may be seen that neuralgia, bronchitis, and intermittent fever rank high as causes of sickness, while we all know that those diseases do not rank high as causes of death

HEALTH IN MICHIGAN, MAY, 1887

Reports to the State Board of Health, Lansing, by regular observers in different parts of the State show the diseases which caused most sickness in Michigan during the month of May (four weeks ending May 28), 1887 as follows

NUMBER OF REPORTS RECEIVED 221		For preceding month
Diseases, Arranged in Order of Greatest Prevalence	Per cent of reports stating presence of disease	Per cent. of reports stating presence of disease
Rheumatism	71	79
Neuralgia	67	73
Bronchitis	57	64
Consumption of lungs	51	58
Intermittent fever	49	52
Tonsilitis	47	54
Influenza	39	43
Pneumonia	33	42
Diarrhœa	30	30
Remittent fever	30	30
Erysipelas	29	28
Measles	28	22
Inflammation of kidney	19	22
Inflammation of bowels	15	17
Whooping cough	13	11
Cholera morbus	11	4
Dysentery	9	7
Typho malarial fever	8	12
Inflammation of brain	7	4
Diphtheria	6	4
Puerperal fever	5	7
Cholera infantum	5	2
Cerebro spinal meningitis	5	2
Scarlet fever	5	9
Membranous croup	4	6
Typhoid fever (enteric)	3	3

For the month of May, 1887, compared with the preceding month, the reports indicate that cholera morbus increased, and that pneumonia, influenza, rheumatism, bronchitis, consumption of lungs and tonsilitis decreased in prevalence

Compared with the preceding month, the temperature in the month of May was much higher, the absolute humidity was much more, the relative humidity was about the same, the day and the night ozone were more

Compared with the average for the month of May in the nine years, 1879–1887, intermittent fever, remittent fever, consumption of lungs, scarlet fever, diphtheria and diarrhœa were less prevalent in May, 1887

For the month of May, 1887, compared with the average of corresponding month for the nine years, 1879–1887, the temperature was higher, the absolute humidity, the relative humidity, and the day ozone were more, and the night ozone was less

Including reports by regular observers and others, diphtheria was reported present in Michigan in the month of May, 1887, at thirty places, scarlet fever at thirty two places, typhoid fever at four places, measles at fifty places

Reports from all sources show diphtheria reported at five places more, scarlet fever at seven places less, typhoid fever at four places less, measles at fourteen places more, in the month of May, 1887, than in the preceding month

Lansing, June2, 1887 HENRY B BAKER, Sec'y

2 Records of deaths are very valuable for purposes of study, but as indications of existing dangers they are not as good as reports of sickness After the deaths have occurred, have been reported, and published, the time has passed for best guarding against the diseases which caused the deaths On the other hand, prompt reports of sickness enable a State Board of Health to aid local health officers in restricting dangerous communicable diseases, and the publication of the facts concerning such sickness would be of much greater value to the people of the locality and to the health officers who would receive the reports in exchange, than are the present reports of mortality statistics

INVESTIGATION OF PRACTICAL RESULTS OF SANITARY WORK

Collective investigation can be successfully applied to many other results than those of the different modes of treatment of diseases For instance, I show a diagram exhibiting, graphically, the results of different modes of action with a dangerous disease of children, namely, diphtheria, the facts having been reported, immediately after the outbreak closed, by health officers, to the State Board of Health, not exactly in accordance with the plan of cooperation by government and physicians, which I have recommended in this paper, but nearly so, because as yet the health officers have too little compensation for such official reports to entitle the government to have credit for the entire work The evidence, when compiled and graphically shown, seems to me to be of immense value as a guide to proper efforts for the prevention of sickness and deaths The diagram shows that in 102 outbreaks of diphtheria in which isolation or disinfection, or both, were neglected, the average number of cases was 16 18, and the average deaths were 3 23, while in the 116 outbreaks in which isolation and disinfection were both enforced the average cases and deaths were only about one fifth as many, indicating a saving of about three hundred lives and 1,545 cases of sickness from diphtheria The inference is strong that if this was true of one or two hundred outbreaks of diphtheria in Michigan in 1886, it may be found to be true in other States and in other years, in which case the knowledge gained by the investigation ought to be of immense utility in guiding to the saving of human life and health

DISCUSSION

DR H C MARKHAM, of Independence, Iowa, thought this paper should give an impetus to our efforts at reporting

DR A N BELL, of New York, asked whether local conditions could not be included in Dr Baker's charts Many places of equal temperature would vary greatly in disease rate, on account of local conditions

DR J M ALLEN, of Liberty, Mo, thought that the States fail to discharge their duty in the matter of providing means for these investigations In the present instance, therefore, we owe the State of Michigan a vote of thanks (as well as Dr Baker), for its action has been exceptional

Remarks were made by others, showing the extreme difficulty of influencing State legislators to act

Dr Baker said we must go slowly, but in time we can get at what Dr Bell suggests Money will be given more willingly when this work is also done in other States Michigan has done well in this matter since 1876 Massachusetts carried on the work one year and then dropped it

THE PROPRIETY AND NECESSITY OF STATE REGULATION OF MEDICAL PRACTICE

Read in the Section of State Medicine, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887,

BY PERRY H MILLARD, M D,

FIRST VICE PRESIDENT AMERICAN MEDICAL ASSOCIATION EX PRESIDENT MINNESOTA STATE MEDICAL ASSOCIATION SECRETARY MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

In the year 1237 the college at Salino, which was founded early in the eleventh century, instituted a series of regulations to the effect that no one should practice physic who had not studied philosophy three years and physic five, and had obtained the license of the college after undergoing an examination at the end of such period Very similar regulations were shortly thereafter adopted by the English universities, and the standard of medical knowledge and education was thereby considerably raised, and a great impetus given to the pursuit of medicine The first degrees in medicine can be traced back to the year 1384

We find by comparison, that one hundred and fifty years before degrees or diplomas were granted, the universities licensed candidates to practice only after they had pursued philosophy three years and physic five, and that six hundred and fifty years thereafter, in 1887, the requirements of 73 per cent of the schools of the United States require only two courses of lectures and three years' study It would, however, be unfair for me to omit the startling fact that a certificate of good moral character is a *sine qua non* from all the schools of this country

The first law regulating the practice of physic in the United Kingdom was enacted in 1511 The practice of physic at this time was largely conducted by the ignorant portion of the artisan class Degrees, however, conferring the right to practice, were held in very high esteem by the people

The progress of medical knowledge during the seventeenth century has been ably described by Mc Cauley, in vol 1, page 310, of his History "Medicine," he says, "which in France was still in abject bondage and afforded for Molière an inexhaustible subject of just ridicule, had in England become an experimental and progressive science, and every day made some new advance in defiance of Hypocrates and Galen The attention of speculative men had for the first time been directed to the important subject of sanitary police "

To that period belong the chemical discoveries of Boyle, and the first botanical researches of Sloan One after another, phantoms which had haunted the world through ages of darkness, fled before the light, and astrology and alchemy became jests Upon research I find that in ancient times effective medical legislation and higher medical education progressed hand in hand After extensive research I am unable to find that any court or legislative body in the British Isles or Continental Europe ever questioned the propriety of effective medical legislation

It seems quite absurd that the propriety of regulating the practice of medicine should be questioned by any respectable portion of the profession of this day My experience, however, teaches me that such opposition is quite pronounced with a few Their principal reasons for such opposition lies in their misguided interpolations of the functions of a republican form of government, and an extreme conservatism in all matters pertaining to their chosen profession Those of us who have been missionaries in this work of reform for some time have not infrequently found the representations of many of our reputable medical schools working arm in arm with the long-haired quack, in their endeavors to strangle the crudest forms of legislation I make the broad assertion that practically the only opposition to effective medical legislation in this country comes from the profession itself, and that this opposition comes principally from the representatives of the seventy-nine medical schools of the United States, that continue to graduate men upon the courses of lectures of twenty weeks' duration each It is unnecessary that I should point to New York, Illinois or Minnesota to verify my assertion It is certainly the duty of the chosen representatives of the people, the legislature, to protect an ignorant and credulous public from empiricism and imperfectly educated medical men and women No profession or vocation is allied so closely to his material interests, yet, in the selection of a medical adviser the community, not infrequently, cares but little for a man's actual medical ability The masses of the community, in the selection of a family physician, make it upon personal grounds alone Were one of us stricken by disease or accident in the streets of this city, we would probably obtain more skillful treatment at the average hospital than at a friend's house upon the most fashionable avenue The propriety of the regulation of the practice of law is never questioned Every State in the Union regulates the practice of law with an iron hand The attorney that defrauds his client has his license revoked, and there is no complaint thereat Ecclesiastical councils regulate the actions and utterances of their clergy by canons quite as strict as in the days of Martin Luther, and the courts endorse their findings with the precedent of the common law as their argument In the cities, the construction of our homes, even, is superintended by the sanitary police

It is, however, ordained that in our profession, the noblest of them all, we shall be left to a competition that is intolerable to an educated man I find upon examination of the literature of medical legislation, that the United States is the only civilized country that is devoid of restrictions regulating the practice of medicine There are at the present time, however, about thirty States with so called medical prac-

tice acts The new acts of Minnesota and Virginia are the most nearly ideal of any, as they are a deadly blow at the cheap schools of this country They fail to recognize the diploma of any school, and examine all parties commencing the practice of medicine

The laws regulating the practice of medicine in Illinois, West Virginia, Minnesota, Missouri and Iowa, have accomplished much in certain directions Their efficiency has been very apparent in weeding out the itinerant quack and undergraduate In Minnesota the number of undergraduate practitioners has been reduced from 37 to less than 8 per cent in four years In Illinois the reduction has been quite as great It is the experience of these boards that the average American diploma does not command the respect or confidence of either the profession or public They find that, as a general rule, colleges are private corporations, operated by and in the interests of a few individuals, whose personal and pecuniary interests—acting with the tendencies of competition—have brought about a state of affairs in which a diploma has practically ceased to furnish any reasonable presumption of respectable professional acquirements

We find the number of graduates in this country since 1880 to be 27,000, and the number of practitioners of medicine about 100,000 This gives us an increase of the number of physicians at the rate of 5 per cent, to an increase of population of less than 2 per cent

In short, the number of graduates of medicine in this country since 1880 closely approximates the combined output of the medical schools of the British Empire, France, Austria and Germany, combined We find that the system of placing the licensing power in the hands of a body directly responsible to the people and entirely independent of and disconnected from the teaching bodies, is the one which prevails in almost every civilized country in the world We have in the practice of medicine in the United States to-day, one physician to every 755 inhabitants They have in England and Hungary one physician to every 1666 inhabitants, in Italy, one physician to every 1639 inhabitants, in Austria, one physician to every 2932 inhabitants, in Germany, one physician to every 3225 inhabitants, in France, one physician to every 3780 inhabitants, in Sweden, one physician to every 7909 inhabitants It will, therefore, be seen that the proportion of physicians to the population is ten times as great in this country as in Sweden, four times as great as in France, Germany and Austria, and twice as great as in Great Britain, Italy and Hungary

The number of medical schools in this country is on the increase, and this increase is not in response to the demands of either the profession or public Of the 130 medical institutions in this country, less than one dozen are in any way endowed Seventy-nine colleges of this country graduate men upon two courses of lectures and three years of pupilage We find by a report of the United States Commissioner of Education for the year 1881, that there are $2,672,490 invested in the ground, buildings and apparatus of the medical schools of the United States The amount of productive funds of these schools is $266,193, and the annual income from investments only $22,000

When we examine the facilities and demands of this country, with those of the British Isles and Continental Europe, we necessarily conclude that the foreign schools exact too much, or that our system is painfully crude and lax The Commissioner of Education remarks that, considering the enormous amount of knowledge that has been accumulated respecting the proper treatment of disease, its prevention and its nature, the impression becomes irresistible that we have been influenced by our national impatience and furious haste in this matter, as in many others, and that we have allowed the students to dictate the length of time they are to study, instead of obliging them to prepare suitably for this important course of instruction and to spend enough time to receive it properly and retain it securely I can but conclude that the low standard of medical education and the absence of uniform legal requirements by the respective States, is the cause of the overcrowded condition of the profession of this country

Dr Rauch, in his "Eighth Annual Report," asserts that there are from 1,500 to 2,000 more physicians in practice in this State than are necessary to supply the legitimate demands for professional services, and who are not earning a comfortable livelihood by legitimate professional exertion

How to prevent the flooding of this country with half educated medical men, will be the vital question with the profession in the coming decade I believe the only efficient remedy lies in efficient medical legislation Having this, the cheap two course school cannot continue to exist With efficient Boards to examine all parties commencing the practice of medicine, a school will best be known by the proportion of its alumni that are able to pass the required examinations, instead of by its numbers and flexible curriculum The profession has been aiming its arrows of criticism at the schools the past decade, and the product of their labors has not been commensurate with their demands These schools are perpetrating a rank injustice to the schools that are striving to exist by enforcing a curriculum that commands the respect of the profession They are perpetrating a similar injustice upon the masses of the profession and the public, and unless it ceases in the near future, I predict a revolution of sentiment that will swing the pendulum to an opposite extreme The present aspect of medical legislation in this country is painfully unsatisfactory We have not an ideal Medical Practice Act in any State in the Union The nearest approach thereto is the new Act of Minnesota By the provision of this Act, every person commencing the practice of medicine must pass an examination and furnish satisfactory evidence of having taken three full courses of lectures of not less than six months' duration each

Under existing circumstances, it is our duty to secure efficient medical legislation in every State in the Union The essential features of such legislation should require a minimum of literary and profes-

sional acquirements The time of study should be not less than four years, of not less than three full courses of lectures of six months' duration each The respective Boards should be empowered to refuse or revoke licenses for chronic inebriety and grossly dishonorable conduct The power conferring the right to refuse or revoke a license should only be used in flagrant cases

The respective Boards should be appointed by the Governor and confirmed by the Senate The term of service should be three or five years, and no member be allowed to serve to exceed two terms in succession The Governor, in the selection of members constituting the Board, should aim to obtain the most intelligent and honorable gentlemen at his command

It is proper that established schools of practice should have representation upon the Board, but the examiners should confine their examination to questions common to all schools of practice All examinations should be held in public, and made a matter of record The several papers should be accessible to properly interested parties at all times

In conclusion, gentlemen, allow me to direct your attention to the social and financial status of the medical professson of this country Had we been alive to our interests, our present environment would have been far different, the pursuit of medicine would offer better inducements to the educated masses today Finally, let me insist upon a renewal of our zeal in behalf of our material interests, and cooperate in obtaining at the hands of the legislatures of the different States such regulations of the practice of our profession as will place the standard thereof upon a citadel of greater strength and power

DISCUSSION

Dr James E Reeves, of Wheeling, W Va, remarked upon the importance of the paper, but advised caution in making a common standard for the practitioners of all communities There are some communities where a man of first class medical qualifications could not live It would not pay such a man to settle down in a community where there are only forty or fifty inhabitants, and they of the common class Therefore such a community might be left without a physician The demand regulates the supply Provision must be made for the out of the way places He would therefore counsel to go slow and to exercise judgment in the matter of a standard, if the same questions are to be asked of all applicants for license to practice

Dr J M Allen, of Liberty, Mo, suggested that there should be a supervising college of the United States Each State should have its standard, and there should be but one power in the State for granting diplomas

Dr W L Schenck, of Osage City, Kansas, said In Kansas we have no medical school, and want none until the State can endow one without regard to the number of students

A resolution was passed appointing a committee of five, to report at the first meeting of the Section next year, to frame a bill for recommendation to different States, regulating the practice of medicine This committee consists of Dr P H Millard, Dr H A Johnson, of Chicago, Dr R H Plummer, of California, Dr Geo B Belt, of Massachusetts, and Dr C W Dulles, of Pennsylvania The committee was instructed to report to the Section on the first day of the next annual meeting

---

THE TREATMENT OF MALARIAL FEVERS IN THE INFANT AND THE YOUNG CHILD

Read in the Section on Diseases of Children, at the Thirty-Eighth Annual Meeting of the American Medical Association, June, 1887

BY W B LAWRENCE M D,
OF BATESVILLE, ARK

As a great majority of my cases of sickness in children have been of malarial origin, I will at least make an attempt to give some of my ideas, or rather mode of treatment, of such diseases I said a great majority of my practice is of this character, which, no doubt, is correct, as I can only call to mind two cases of diphtheria treated, and I have been through a mild and short epidemic of scarlet fever in a practice of ten years Still, at the same time, I do not wish to convey the idea that our part of Arkansas is more pregnant with malarial poison than many other portions of the United States, which are not considered uninhabitable

My home is an old town, and a place probably of 2000 inhabitants, with the surrounding country thickly settled, and the town several hundred feet above the sea level, situated on quite a hill, at the foot of which runs a beautiful and rapid river Still the Eastern winds from the great Mississippi Valley bring us more or less of this poison, the year around Flint says this poison shows itself in the shape of the different fevers in the interior Valley of North America The regions in which it has most frequently prevailed, are the level portions of Alabama, Mississippi, Louisiana, the Southern Shore of Lake Michigan from Chicago around to St Joseph River, and Lake Erie and Lake St Clair, from Lake Huron to Lake Ontario near estuaries of the creeks and rivers So you see from this that when we leave home, we do not always leave the malaria behind us

My desire is only to speak of the treatment of these fevers according to the By laws of our Association, I would not have the time, if I felt in the least competent or inclined to undertake the work of saying anything of the clinical history, anatomical characters, causation, diagnosis and prognosis Many of us are so unfortunate as not to be able to write a very simple and interesting article on any topic or disease, although we have had the opportunity of treating and watching these diseases in all of their many forms and stages, and if such be true, how much less able are we to write of something which we have never seen, or had any dealings with, except what others have told us, or in other words, we must give our own ideas and experiences, and at the same time lay them right open for criticism After some persuasion, I offer this as an effort to add something to our Section Let each one have am-

bition enough to bring it forward Men of pride do not like to lag and see any of their undertakings sink into insignificance or die So, if we have any pride for the much neglected Section, each one must attend and offer something And another reason for attempting to present this subject, is this, that our standard text-books on diseases of children, such as J Lewis Smith and Ellis & Vogel, say but little Certainly, we find quite an exhaustive article on the subject of the treatment of malarial fevers in the great works of Flint and other good authors, but they do not speak specially concerning the fevers, or the treatment of such in infancy and childhood, and certainly articles applying strictly to such would aid the practitioner very much in his treatment

Dr J Lewis Smith, in his most instructive and readable work on "Diseases of Children," under the head of "The Treatment of the Different Malarial Fevers," covers the whole subject in forty or fifty lines, and does not mention more than six or eight different drugs Vogel and others go over the subject in about the same manner Most of them place but little importance to the management of these fevers in any form In most of the different types of these fevers, and especially if bordering on a pernicious form, they certainly require much attention, although the patient may not be in a dangerous condition, for this reason the little fellows suffer so much with sick stomach, restlessness and often accompanied with convulsions With these symptoms, these children's parents cannot be satisfied until some relief is afforded, and especially during the convulsive period

Numbers of writers will say that in all forms of these fevers, cinchona or some one of its preparations is the "sheet anchor" Admit such to be the case, keeping the anchor in the patient's stomach is often a task of itself, and very frequently we fail in the attempt Another assertion is this "Open the bowels with a mild purgative or an enema" We will try to show that such treatment in some cases, will not afford any relief, for the mild purgatives, such as senna, rhubarb, castor oil and magnesia often cannot be tolerated, and can in a more pernicious type after acting on the bowels, afford but slight relief I believe such to be the case

I will first endeavor to speak of the treatment of the milder forms of intermittent fever, either of a quotidian, a tertian or a quartan *First*, in the simple or mild intermittent fever, and I presume we are to understand by this fever one wanting in grave or alarming symptoms, I do not think it necessary but to barely mention the fact that the bowels should be opened, and one of the preparations of quinine given in doses according to age, which of course, means a sufficient quantity

Of pernicious intermittent fever, this form in many cases can be prevented, and many lives saved, by attention during and after the first paroxysm, that is we prevent others of a grave and maybe a fatal type When the fever becomes pernicious, we have two objects in view, namely to see our patient through the existing paroxysm, and to keep off another

In the first of these, suppose our case an infant, for example, say 4 months of age In the cold stage, my experience is that they remain for a shorter time than older children or adults, and that we can more quickly, and with less work bring about reaction In the 4 month infant, or maybe some older, this is generally done by applying heat to the surface or wrapping the child in a blanket But we may have much trouble with this aged infant in the hot or fever stage, and more especially if it goes into convulsions Should the fever go very high, aconite nitre, paregoric and bromide of potassium in water, dose according to age, the sick stomach which we frequently find to be very annoying, is oftenest relieved by bromide of potassium or a creasote mixture If convulsions come on, put the little fellow in a warm bath or wrap in a warm wet sheet or cloth of a proper kind, move the bowels as soon as possible by enema, and if you can't give the antispasmodic by the mouth, administer it per the rectum, such as hydrate of chloral or bromide of potassium As soon as the sick stomach subsides and the temperature is on the decrease, as a general rule, I think it quite necessary to give an active purgative Not always, but quite often, order mercury in the form of calomel, and in these extremely pernicious attacks, I have not been able to find anything to take its place I will say just here that I have never administered a dose of mercury in any form to either an adult, child or infant, that did the least harm in the way of salivation, in fact I never had but two of my cases in the least affected by it, and these very slightly and for only a short time

As soon as the patient can bear quinia, we begin it, whatever the type, and if quotidian, we have no time to lose So we try to give our 4 and 6 months', or probably 12 months' infant a sufficient quantity of quinia sulph We have tried it in many forms, not as the saying is, to "disguise the taste," but rather to prevent nausea, such as elixir of licorice, lavender, malt, aromatic elixir, and also the cascara cordial In some cases all fail, however, as a general rule, I find the licorice the surest, I think the cascara cordial acts too much on the bowels On account of this sick stomach in a number of cases are forced to give the anti-periodic in another mode or channel, that is *per rectum* or by inunction, and with our little syringe and quinia we get much satisfaction from the rectum plan Of administering quinia by inunction, I will say but little I frequently order in large quantities, still I am not able to say how much good it does in preventing a paroxysm, but think it aids in many cases to a certain extent I have never ordered it in anything but pure hog's lard I will mention a case as an example I have a little niece 2½ years of age She has had two or three attacks of ordinary intermittent fever In the first spell, I ordered sulphate of quinine in an anti nauseating mixture, but she could not retain a single dose, then I ordered it by inunction, which prevented a second paroxysm of anything like serious nature The child is now 2½ years of age, and has never taken but the one dose by the mouth, which was vomited I have several times used the inunc

tion, and it looks very much as if it has prevented pernicious attacks

Concerning the treatment in this form of fever in the young child, say 5 or 6 years of age These cases we can manage with more satisfaction to ourselves than we could in the infant, for the reason that it will allow more to be done for its relief In the cold stage we will find often more urgent treatment required than in the little fellows I should, in the first place, see that the heart's action is kept up towards normal, if possible, with stimulants, they may be alcoholic, brandy or whiskey will suffice, but if they fail I should try ether, and with it ammonia, by inhalation and mouth I have also very frequently given nitrite of amyl by inhalation, dose ℥ ij–v in a handkerchief is a very convenient mode of administration, and I have found this to to be a very valuable remedy In fact, I think it one of the best stimulants in this stage of the disease In some cases, at this age, I have given morphine hypodermically, and especially in cases suffering with sick stomach and restlessness, I find that it affords great relief, brings about quiet, and aids good circulation very much, and in many cases is the only thing that will give relief I have given chloroform in from eight to ten minims, but with little good, if any While administering the above remedies, or some others, I order mustard in the form of plasters to the ankles and wrists and, at the same time, friction with flannel cloths

Now, after helping to nurse our patients into a hot stage, we, if this hot stage becomes serious, try to cool them down In some cases this is the alarming period, in others just the reverse I give about the same febrifuges as mentioned heretofore Sometimes I resort to the tr verat viridide I have never given antipyrin to children with those fevers, I have ordered it this winter and spring in a few cases of pneumonia with a very high temperature, say 104° and 105°, it always reduces the temperature, but I think prostrates more than veratrum I have found but little if any good from quinia in this hot stage I almost invariably find it necessary to employ quite an active purgative and give it as soon as possible I have given rhubarb in different forms, powder and fluid extracts, senna and podophylin, and many other drugs I have not found anything to take the place of calomel If you have a quotidian type you have no time to spare, so administer the purgative, and while the patient is taking it, if the stomach will tolerate, give within 12 or 15 hours, gr xx of quinine We may be compelled in some cases to give it as suggested in the cases of the infants If the case require anti spasmodics, give them, or about as suggested for the infant, only the dose in proportion to the age

In the treatment of remittent fever, so soon as you are sure you have this form of fever to treat, there is that old remedy which is required in all cases, namely, cinchona, or its equivalent, quinia In sthenic cases I should employ a light febrifuge, and as soon as the fever gives away, give a proper amount of quinine, for restlessness, in insomnia, give bromide of potash and comp pulv ipecac, open the bowels freely, apply frequently cool cloths to the head, and order a warm mustard foot bath These remedies often do much good

We may be forced to do more than this if the fever takes on a pernicious form The patient may require chloral hydrate or morphine to quiet him, of a mild, mercurial purgative, frequently combined with santonine, followed with oil To break up an attack of remittent fever without these things, is often impossible I have had many a patron to say "*Doctor you will have to come to our child It has had fever for three or four days, and a 'high one' We cannot break it We have given pills or oil, or probably one, or half a dozen domestic purgatives, and followed with a good amount of quinine for two or three days, but our treatment does no good*" And if I find such to be the case, I generally give the calomel and santonine, and in a number of cases never make a second visit The fever gives away in a number of instances within 10 or 12 hours But frequently in a child of from 5 to 8 years of age, this fever will continue in spite of all our treatment, for 10 or 15 days, and maybe longer After active treatment for 3 or 4 days, and the symptoms point to such a continuation, we begin a treatment similar to that of typhoid fever, that is, use tonic doses of quinine and one of the acids A mild febrifuge, if necessary, keeps the bowels regular, and light stimulants after fever has continued some days Order iron to be given for a short time after the fever has given away

I will only say a few words of the treatment of that pernicious form of intermittent commonly called in the South, "Hæmorrhagic Malarial Fever" It is always considered dangerous I have never seen a case of it in the infant, and very seldom do we see a case in our part of the State, either in the adult or the children, however, occasionally in both Our plan is to keep the patient well cared for in blankets, use mustard freely in form of plasters over the region of the kidneys and stomach, give active cathartics but very little quinine, it seems to aggravate the disease The restlessness and sick stomach are best controlled by hydrate of chloral or bromidia During the passage of blood so freely, give buchu, fluid extract of, and hyposulphite, dose according to age

I would like to say something of the treatment of chronic malarial poison, but do not wish to be tedious to the Section, and for that reason, am afraid I have not done this subject anything like justice

MEDICAL PROGRESS.

THE AFTER TREATMENT OF DIFFICULT LAPAROTOMIES — P MULLER, of Berne, reports a case in which adhesions took place between the anterior and posterior walls of the abdomen over an extent of 25 cm , in such a manner as to include a knuckle of small intestine In order to prevent such accidents he advises the avoidance of bandages which exert pressure in all cases where there are extensive wound surfaces in the peritoneum In the second place he

proposes to prevent adhesions by filling the abdominal cavity after laparotomy with a sterilized neutral solution He employed this method in a case in which he found extensive adhesions, using 2,400 grams of a 0 7 per cent solution of salt, which he poured into the abdominal cavity through a drainage-tube introduced into the upper angle of the incision This sufficed to fill up the cavity, occupying as much space as the tumor had previously taken up Soon after the operation the patient was seized with dyspnœa and the pulse ran up to 150 Then profuse diaphoresis and diuresis gradually relieved the artificial ascites, which disappeared by the sixth day The results with regard to the prevention of adhesions were entirely satisfactory The writer believes that it is unsafe to employ as large a quantity of the solution as he did in his own case, but he intends to experiment in the same direction with smaller quantities, to be thrown in every 3 hours by means of the double canula, or to be employed by means of permanent irrigation —*Centralbl fur Gynak*, No 25, 1887

THE EFFECT OF HYOSCINE HYDROCHLORATE — KOBERT, of Dorpat, Russia, is quoted as follows by *Schmidt's Jahrbuch*, 1887, No 7, in the results of his use of this drug as a sedative

Hyoscine, when given in large doses, is excreted as such by the kidneys A small amount of the urine of an animal thoroughly under the influence of hyoscine, when dropped upon the heart of a frog which had been poisoned by muscarine, will cause the heart which was quiescent to beat Hyoscine is thus an antidote to muscarine In the same way, muscarine, by its stimulant power over the pneumogastric, will cause a heart to beat which had been stopped by hyoscine The effect of the drug is the same upon the human subject as upon the frog In the case of a patient with melancholia, whose pulse was slow, an injection $\frac{1}{60}$ of a grain produced a very perceptible acceleration In small doses, of $\frac{1}{120}$ to $\frac{1}{60}$ of a grain, hyoscine is a weak narcotic to healthy beings Numerous observations made upon the large numbers of patients at the Dorpat Clinics for Insane Patients, have proved its excellence as a reliable hypnotic, when given subcutaneously in doses of $\frac{1}{120}$ to $\frac{1}{60}$ of a grain of the hydrochlorate A peculiarity of the use of hyoscine was the absence in the cases noted of all ill after-effects produced by the drug —*Therapeutic Gazette*, Aug 15, 1887

STROPHANTHUS IN HEART DISEASE —MR MONTAGUE D MAKUNA says Having recently had occasion to prescribe it in two cases with excellent results, I take this opportunity of bearing testimony to its action as a certain cardiac tonic and powerful diuretic, with a hope that it may induce others to use it when they find themselves in a dilemma, and feel anxious to resuscitate the failing action of the heart I have used it firstly in four cases of angina pectoris, in two cases associated with dilatation of the heart A fortnight ago I was hurriedly called to see a young man, aged 25, in an agony of pain, with tumultuous action of the heart Within five minutes of the administration of a five-minim dose his breathing became quiet, pain disappeared, and the rhythm of the heart's action was restored In two cases of dilatation of the heart, the patients took five minim doses three times a day with marked benefit

Secondly I have used it in two marked cases of fatty degeneration of the heart I had a patient, aged 45, under treatment when Prof Fraser read his paper, and whose life was altogether despaired of at the time The state of degeneration was much advanced, and she had some general dropsy She lived to take it for nearly eight months—five minim doses three times a day, but about six months after its first administration the cardiac response became more and more feeble, until she succumbed I believe her life was prolonged with some comfort solely by the use of strophanthus I have at present a case of fatty degeneration of the heart in a woman, aged 49, accompanied by attacks of angina, much dyspnœa, and palpitation I have administered to her five minim doses every hour till the action of the heart is quieted and the breathing rendered easy She now takes it three times a day in the form of a mixture, which can be safely trusted to the patient, namely Tinct strophanthus, f℥iss, extract ergot liq f℥vj, spirit chloroform, f℥iss, aquæ lauroceres ad f℥iv, a teaspoonful three times a day in a wineglass of water The latter patient has taken this mixture during the last week with marked benefit

I have had, unfortunately, the experience of tincture prepared from other parts of the plant than the seed, in two cases which eventually proved fatal Judging from actual observations at the bedside, I cannot but pronounce it as uncertain in action and totally unreliable, notwithstanding the assurance of the druggist of its equal efficacy when the supply of the seeds had gone out of the market at the end of last year —*British Medical Journal*, Sept 3, 1887

NAPHTHALIN IN PILL FORM —BERNBECK has found that a pill covered with elastic collodion is especially useful in administering this drug His formula is

℞ Naphthalini resublimat , 10 parts
Rad althææ pulv , 5 parts
Mucil gummi arab , q s
Ut fiant pilful 100
Dry without heating, and cover with elastic collodion
Sig Two or three pills three times daily

The remedy is especially useful in gastro intestinal catarrh The advantage of the collodion coating is in the fact that it is dissolved in the intestine and not in the stomach, and that no unpleasant taste is experienced from eructations For the success of the collodion coating it is essential that the pills be carefully dried before its application —*Deutsche Amerikanische Apotheker-Zeitung*, June, 15, 1887

MARINE SALT IN ANÆMIA —HEGAR has used hypodermatic injections of a 6 1000 solution of marine salt, pure and recrystallized, with good results in anæmia The condition of the circulation was improved, as was shown by sphygmographic tracings —*Revue de Therapeutique*, August, 1887

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE INCLUDING POSTAGE

PER ANNUM IN ADVANCE $5 00
SINGLE COPIES 10 CENTS

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned When neither is accessible, remittances may be made at the risk of the publishers by forwarding in REGISTERED letters.

THE NINTH INTERNATIONAL MEDICAL CONGRESS

That the many readers of THE JOURNAL may know the real character and success of the recent International Medical Congress in Washington, we copy the following leading article from the London *Lancet* of September 24, 1887, pp 617 and 627 Certainly no higher or more impartial authority could be invoked *The Lancet* says

"The success of the Ninth International Medical Congress is a matter for thankfulness The interruption of the series of Congresses would have been little less than a calamity and a disgrace for the profession in all nations Any serious imperfection in the meeting, either as respects numbers or the character of the discussions, would have been but little less unfortunate But the Congress has been held under most honorable auspices, the famous hospitality of the United States has been fully realized, and those who went great distances to attend the Congress have been amply rewarded, and will return to their various countries and duties with higher impressions of their calling and deeper convictions of its progress, both on its scientific and its medical side We cannot but rejoice that our own country was well represented in many of the Sections, the names of many well-known English physicians and surgeons will have been noticed in the reports which were received by cable from our special correspondents at Washington We confess that we read the report of the concluding proceedings of the Congress with the most pleasurable emotions, and not least the remarks of the English members A break down of the Congress in Washington would have been only a less acute pain to us than a break down in London And we accept the concluding speeches of our countrymen and of our *confrères* of Berlin and Paris, Dr Martin and Dr Landolt, and others, as proof that the Congress has been worthy of its predecessors, that it contained a larger gathering of foreign members than any of them, and that it is calculated to promote the advancement of our art Those in the United States who have worked to this end, in spite of much discouragement, well deserve the gratitude which was accorded to them by formal resolution We have purposely abstained, in our allusions to the Congress, from pointedly referring to the domestic differences among our brethren in the States, which threatened to seriously mar the success of the Congress, if not to prevent it altogether Those who persevered in spite of all opposition, and who have carried through the Congress so successfully, may well be satisfied They have done a great service to their country and to their profession in all countries It is not necessary for us to say that they committed no faults and made no mistakes Such praise is not for mortals in a world so full of 'spilt saltpetre' as ours But they have carried through the Congress, and we thank them There is yet one other service they can do in any official action that now devolves upon them, to strive to obliterate the last relics of discord, and to hand on the light of truth and charity, undimmed and unqualified, to those in Berlin on whom will now rest the burden of responsibility for the next Congress They can well afford to be magnanimous, and to help to make the representation of the States at Berlin so complete as to bear no traces of recent divisions

"The scientific value of the addresses and papers read at the recent Congress cannot be estimated till we have seen them in full On the whole, judging from abstracts of the papers and discussions, we are inclined to say that they have been practical rather than theoretical, and have had reference to useful rather than transcendental aspects of medicine Neither, so far, have we met with much indication of original matter in the papers But this is no dispraise It was meet that in the most practical nation in the world papers and discussions should take a practical turn, and deal with questions at their practical point No branch of medicine can be said to have been neglected, from that which deals with the brain to that which deals with the risks of decayed teeth, including, by the way, several instructive cases of pyæmia The statistics of vaccination were much advanced in a paper by Dr Josef Korosi, Director of Communal Statistics of Buda Pesth (to which we hope to make more special reference), and other questions of Public Medicine were made subjects of interesting discussion Every branch of medicine was well represented—notably the ophthalmic, the gynecological, and the dermatological, so that we venture to forecast that the volumes of the Transaction Reports will have considerable practical importance

"Notwithstanding that the City of Washington is, like most other cities, liable to suffer an annual desertion by the most influential part of its population during the early autumn, the ninth meeting of the International Medical Congress has been one of the most successful of its kind We shall not err in saying that as a social undertaking merely, without regard to its professional aspect, this transatlantic

gathering holds a place not second in importance to anything of a similar character that has happened, or is likely soon to happen, on this or that side of the dividing ocean As an assemblage of medical practitioners and teachers met together with a common purpose of comparing and correcting the results of observation and invention, of devising new plans for future investigation, and of applying new modes of treatment in the art of healing, its significance is equally remarkable With the single exception of London, no European capital has attracted so many representatives of medicine and surgery since the International movement first originated Successful in point of numbers, the conference has not been less successful in possessing in more than one particular a thoroughly representative quality It has been in the widest sense International Almost every civilized people, besides races which might by courtesy be included in the same category, have contributed towards its membership The four continents have given of the skill which is available for the treatment of disease in their civil practice, the military and naval services have subscribed each its quota of men and of material for discussion Again, as regards the subject matter, it is almost superfluous to point out the illustrative diversities of study by which the sum of medicine can be viewed as through so many windows, and to state that each of these has received its full share of recognition in the working programme of the Congress Last, but not least, the whole business and pleasure of this meeting have been administered with a cordial good fellowship truly representative of that spirit of hospitality which happily characterizes the American people and annually admits to the privileges of free citizenship strangers out of every country without distinction President Cleveland and his assessors in the work of Government have been foremost in showing attention to the American practitioners and their guests Not only have they taken an active part in the extra professional work of the Congress, but it is through their influence that Government buildings have been on several occasions available for social gatherings of the members We are happy to recall the fact that in so doing they have but revived the precedents afforded by the conduct of other States, but we appreciate no less on that account the warmth of their generous consideration Nor must we forget to offer an equal tribute of esteem to the American medical press, and to those citizens of Washington who distinguished themselves by affording a similarly handsome hospitality "

Inasmuch as the International Medical Congress of Washington has passed and been freely awarded a high and honorable position with its predecessors by the medical press of other countries, we desire to add only an earnest hope that the medical press of this country will accept the gratifying result, and instead of nursing old prejudices or seeking for imperfections and errors, to which all human beings are liable, will henceforth labor for the unity and advancement of the profession as a whole, and to secure an American representation in the International Medical Congress of 1890, at Berlin, as intelligent and honorable as came from the other side of the Atlantic to Washington in the Congress of 1887

THE CLAIMS OF MEDICINE

A year ago one of our contemporaries spoke of the "Students' Numbers" of the English weeklies as "unmitigated nuisances " They can be so regarded only by those who do not earnestly desire a reform in medical teaching It would be well if every physician, every student, and especially every teacher of medicine in this country, could read these "educational numbers" each year and study in them the English system of medical instruction In England —or we should say, in the United Kingdom—medical study is practically under the regulation of the Government In this country the General Government does not concern itself with medical education, and where there is any governmental regulation or supervision it is that of a State

In the United Kingdom no person is allowed to register as a medical student (and every medical student must be registered) unless he has previously passed, at one or more examinations, in 1 English language, including grammar and composition 2 Latin, including grammar and translation 3 Elements of mathematics 4 Elementary mechanics of solids and fluids 5 One of the following optional subjects Greek, French, German, Italian, or any other modern language, logic, botany, zoology, or elementary chemistry The commencement of the course of professional study is never recognized as dating earlier than 15 days before the date of registration The registration of students is under the charge of the "Branch" Registrars, who keep a full record of the students registered A "Medical Students' Register" is made up and sent each year to the Registrar of the General Medical Council by each Branch Registrar, and this Register is printed and sent to each medical school and hospital

In regard to professional education and examination the General Medical Council recommends that the course of medical study after registration should occupy at least 5 years, if the subjects of elementary physics, chemistry, and biology be included in that period, or at least 4 years if a satisfactory examination in these subjects has been passed previous to registration It is also recommended that at least 4 winter and 3 summer sessions should be passed at a school or schools recognized by the licensing bodies of the United Kingdom At least 3 professional ex-

aminations are recommended "In no case should the examination of a candidate in any subject be conducted exclusively by his teachers in that subject in the school in which he has been educated" "Every candidate for the *final* professional examination should be required to give evidence that he has had sufficient opportunities of practical study, with care of patients, medical, surgical and obstetrical, in hospital, dispensary or elsewhere" With regard to this it may be said that proof that a candidate has had opportunities is not proof that he has availed himself of them

It is said that the profession is more esteemed and looked up to in Great Britain than in this country Is not one reason of this the fact that the British public knows that the medical man must have spent a certain amount of time, and that a long time, in the study of his profession, while in this country the public knows that men are graduated from many medical schools with insufficient qualifications, and after, in some cases, absurdly short periods of study? In Great Britain a medical title is a guarantee of something definite, in America such is not the case, unless one takes the trouble to find out where the individual was graduated—and this the public will not do Laymen are, like professional men, critical, and take much more kindly to assertions which are accompanied and supported by reasons Is there any wonder that the public sometimes questions the vastness of medical science when so many claim to have mastered its principles in two winter sessions? Medical men should not only see to it that members of the profession are properly educated, but that the public is also educated in regard to the real meaning of medicine as an art and a science

We have thus far only outlined the *professional* mental demands of medicine There are also other claims of the profession upon its members A medical man who knows nothing but medicine is very apt to be a one-sided character Medicine demands at least something of general culture An educated physician, like any other educated man, should know "something of everything, and everything of something" The knowing everything of something should be the *work*, the vocation, the finding out something of everything should be the amusement, the recreation, the avocation By regular habits, regular hours (or as regular as possible) and an equable distribution of work and exercise one need not look forward always to summer at the seaside for rest, recreation and amusement Idleness and inactivity are medicines for sick people, but poisons to healthy bodies and minds

Medicine has also certain distinct claims upon those who teach by their writings In this age of much writing and many books, he who would have his writings on professional subjects read must avoid prolixity and verbosity, and state facts and ideas in the shortest and fewest words possible And this leads us to say that the physician who would have some definite mental recreation, and one that will be of real service to him and others, cannot find a more varied or interesting subject than the study of English composition and style, and with this may be recommended the study of modern languages, the value of which is apparent Modern medicine demands that the members of the profession keep pace with her advances, and this they cannot do if they are dependent upon translations for a knowledge of what is being done in other lands

ANTIPYRIN IN ACUTE BRONCHITIS OF CHILDREN

For some months innumerable articles have appeared in current medical literature discussing the physiological and therapeutic action of antipyrin That the drug has a wide range of usefulness is an undoubted fact and yet many practitioners who welcomed it gladly at first are now regarding it with some suspicion because of the occasional toxic effects that they observe from it and with some misgivings because of the failure to obtain expected results from its use There is little doubt but that the drug will obtain a permanent place in therapeutics but we need much more exact information in regard to the indications for its use It is surprising, as FRIEDLANDER points out in a late number of the *Therapeutische Monatshefte*, that among so many articles describing the action of the drug so few have appeared which consider its usefulness in diseases of children Friedlander has observed with care the indications by which the usefulness of the drug can be gauged in individual cases of acute bronchitis in children It is just such observations that are needed to enable the physician to use medicines to the best advantage He says that before using antipyrin he lost many children who were attacked with this disease and its duration was from two to three weeks Since using it the mortality has been wonderfully diminished and the average duration reduced to one week

If the cases of bronchitis are classified according to their amenability to antipyrin two groups must be formed, the first embracing those that are most benefited by the drug, and the second those that receive little aid from it The first group embraces those

who have a temperature of 104° F (40° C) and who are well nourished, the second those that have a moderate temperature, 102° F (39° C), or less, and who are not well nourished Both classes are aided by antipyrin treatment, but the former much more so, as is shown by the following statistics Friedlander says that in a recent severe epidemic of acute bronchitis among children in his neighborhood, he, as well as his fellow physicians, lost 50 per cent of their patients but since he has used the antipyrin treatment he has lost none of his patients belonging to the first category, and the duration of their illness has averaged not more than a week, and the percentage of loss in the second category is reduced to 10 He suggests that the reason why the drug does not apparently accomplish as much good in weak children is because they are not able to withstand its unpleasant side effects, such as the profuse sweating that it induces Usually after the administration of a dose the little patients break out in a profuse perspiration, the temperature falls, they sleep for an hour or so and awake with a feeling of well being The cough is usually looser, and the breathing easier The dosage recommended is for children under 5 and over 2 years, 12 or 13 grains (0 9 gms) Its effect will continue for from 12 to 15 hours and therefore two doses must be given daily To a child 2 years old, or less, 7 grains (0 5 gms) may be given, but only one dose will be needed in the 24 hours During convalescence one-half of the above mentioned quantities are given at a time The treatment of acute bronchitis among children by antipyrin as recommended by Friedlander does not exclude the simultaneous use of expectorants

CONCEPTION AFTER CURETTEMENT

In Pippingskold's clinic the operation of curetting the uterus for fungous endometritis was done 60 times during the years 1872 to 1885 HEINRICIUS reports (*Centralblatt fur Gynakologie*, No 25, 1887) that in 25 of these cases parturition seems to have been the cause of the hæmorrhage, and of these 15 became pregnant after the operation, 5 of the 15 being under 30 years of age, 8 under 40, and only 2 over 40 Of the remainder 1 was a widow 39 years old, 7 were over 40, and the age of 1 patient unknown Of 35 patients in whose cases parturition played no part in the causation of the disease, 1 died, and information is wanting in regard to 6 Of the remaining 28 only 1 became pregnant after operation Most of these patients were approaching the climacteric In 17 cases functional disturbances of the ovaries were the causes of the disease, in the opinion of Heinricius Of the 52 patients whose histories are known 16, or 30 per cent, became pregnant after curetting In 2 cases pregnancy began 5 weeks after the operation, and in 1 case in 8 weeks In his private practice Heinricius has had 1 patient who became pregnant 4 weeks after the operation

TRANSACTIONS OF THE NINTH INTERNATIONAL MEDICAL CONGRESS —The Executive Committee while in session in Washington adopted the following resolutions that may be of interest to many of our readers

"*Resolved*, That all papers read, and the manuscript reports of all discussions, and all illustrations, must be handed in to the Secretary General *before* November 1, 1887, in order to secure a place in the Transactions

"*Resolved*, That notice be given that the *price* of the Transactions shall be fixed at $10, to those persons desiring to purchase, and that such persons be requested to send their names, with the amount, not later than November 1, to Dr E S F Arnold, Newport, Rhode Island, the Treasurer "

GLEDITSCHINE, not Stenocarpine, is the proper name of the new local anæsthetic mentioned editorially in THE JOURNAL of September 17 The *Gleditschia triacanthos*, or thorny locust is the tree from which it is obtained

SOCIETY PROCEEDINGS

AMERICAN GYNÆCOLOGICAL SOCIETY

The twelfth annual meeting of the American Gynæcological Society was held in the Hall of the Academy of Medicine, New York, September 13, 14 and 15, 1887

FIRST DAY—MORNING SESSION

The Society was called to order by the President, Dr A J C Skene, of Brooklyn

An Address of Welcome was delivered by Dr Fordyce Barker, of New York

DR THOMAS ADDIS EMMET, of New York, read a paper entitled

A STUDY OF THE CAUSES AND TREATMENT OF UTERINE DISPLACEMENT

Version cannot be regarded as the disease It is but a symptom If we examine a woman suffering with prolapse, the pulsation of some branch of the cervical artery can be readily detected When the uterus is raised to the health line a sense of relief is

felt, and if it be held there for a few minutes the pulsation ceases If, however, the uterus is raised beyond this point, distress is again experienced Anteversion is certainly not an abnormal position Retroversion to a marked degree is frequently detected through accident where it has not given rise to the least inconvenience With reference to the causes, he wished to refer to the influence of pelvic inflammation in inducing displacement The only fixed point is in front of the neck of the bladder where the sub pubic ligament binds down the urethra Any traction on this point leads to irritation and a desire to empty the bladder This often results from inflammatory adhesions The uterus may be retro flexed or anteflexed, but the traction will be upon the urethra Prolapse is the more usual consequence of pelvic inflammation, resulting from the increased weight due to the obstructed circulation The degree of displacement is usually in proportion to the extent of the cellulitis The effect of peritonitis involving Douglass' cul de sac is to raise the uterus, while versions always result from pelvic cellulitis In cases where the inflammation is confined to the utero sacral ligaments there will be anteversion

In a case of backward displacement the uterus is usually comparatively free, so that the displacement can be corrected with the finger If the organ be held in what is supposed to be its correct position, pulsation will soon be detected in some of the neighboring vessels If a pessary be introduced under these circumstances it will soon be necessary to remove it In extreme anteversion, the displacement cannot be corrected by means of any instrument without making traction upon the utero sacral ligaments, and if this is done inflammation will be the result In the treatment of cases of displacement the result of inflammation the general practitioner should not resort to pessaries, but should, if treatment is necessary, apply iodine, use cotton and glycerine pads and order hot water injections

The pelvic circulation presents certain peculiarities In no other part of the body can so much blood be received in case of disease The veins are without valves, and their course must be tortuous in order to overcome the force of gravity The author had observed that if the uterus be drawn down to the floor of the pelvis and held there, the cervix and vaginal tissue become congested as the result of obstruction of the venous circulation If, however, the traction be increased until complete procidentia is induced, the tissues become blanched as a result of the narrowness of the arteries from the traction

The whole skill in the use of the pessary consists in constructing it of such size and shape that while it relieves the prolapse it will just dispose of the overstretching The relief is not dependent entirely upon relief of the version Its effect is indirect, consisting in the relief of congestion The speaker had also used cotton saturated with glycerine to lift the uterus The quantity used was never more than sufficient to correct the prolapse If a large quantity is employed, it is liable to cause irritation The profitable range for the use of pessaries is not extensive If not employed with great caution and judgment, the effects to the patient may be very serious He believed that nothing can take the place of pessaries when properly fitted and used in the proper class of cases He thought that their field of usefulness was more limited than is generally supposed The displacement should not be corrected on its own account nor until the history of the case has been ascertained No attempt should be made to correct the displacement so long as any evidences of recent inflammation are present In tracing the histories of a large number of women, no instance of permanent cure has been found from the use of pessaries, in cases where there was reason to believe that previous inflammation had complicated the case

Dr Grailly Hewitt, of London, said that the subject of displacements of the uterus had occupied his attention for a considerable period There seems to be a difference between American and English women with reference to the frequency of cellulitis He had not found this complication in a large number of cases of uterine displacement The question of the general causes of displacement is very important The speaker has attributed the sufferings of the patient to pressure by exudation He has not alluded to a point which Dr Hewitt considers important, and that was that the flexure in the uterus interferes with the circulation and causes pressure upon the nerves To this cause he would attribute a large part of the pain Simple straightening of the uterus relieves the discomfort In cases of acute flexion where the sound has been used in the treatment, when the instrument reaches the internal os, this part is found excessively sensitive By completing the introduction and straightening the uterus, the tenderness disappears within 24 hours and does not return

There was something more to be said with reference to the use of pessaries when there is no pelvic cellulitis He agreed that pessaries should not be used if there is acute congestion present, but that there may be cases in which there is contraction and hardness associated with displacement in which pessaries may be very valuable in leading to absorption of the exudation The pessary must, of course, be fitted carefully and properly applied

Prof A R Simpson, of Edinburgh, remarked that it had been suggested that there must be a difference between the females of America and of England with reference to pelvic cellulitis He thought that the difference was more with the mind of the individual who examines these cases The same woman going to several different observers might get a different opinion from each He agreed with Dr Hewitt that the author had not taken a very large view of uterine displacements He seemed to confine himself to the results of inflammation and to displacements occurring in women who had had children We also have displacements occurring in women who have been married two or three years and have not conceived In some of these cases we have inflammation, and this is not to be overlooked Even after we have done all that we could in the way of relieving the inflammation, it is necessary to put the uterus in proper position to fit it for impregnation

DR G BANFOCK, of London, was unable to agree with the author with reference to the frequency of pelvic inflammation Experience is teaching us that pelvic inflammation is less common than we have generally supposed Many of the cases regarded as pelvic cellulitis have been instances where the inflammation was confined to the Fallopian tubes or the peritoneum lining Douglass' cul de sac, and especially the peritoneum covering the Fallopian tubes He had not seen the utility of paying so much attention to the causes of displacement In a case of a broken arm we do not inquire particularly as to the exact manner in which the injury was received So in cases of displacement of the uterus, we need not trouble ourselves with regard to the cause of the trouble The patient comes to be relieved and we proceed to relieve her as best we can His experience was that in the majority of cases perfect and permanent relief can be afforded by the proper use of the pessary The proper adjustment of the instrument is the whole secret After confinement, where there is retroversion, he recommends, where the uterus is not adherent, replacement by the sound and a pessary properly applied Where there is much tenderness it is not desirable to at once apply the pessary, but the congestion should first be relieved Where adhesions have formed the use of the pessary must be set aside altogether

DR T A EMMET, of New York, said the causes of displacement of the uterus are many, and most of them are well known His object was to call particular attention to one class of cases which are overlooked and which are complicated with inflammatory troubles, which will not be discovered unless an examination by the rectum is made This is the reason there is such a diversity of opinion There is no one who uses pessaries more than he does, and in the majority of cases pessaries should be used and nothing else can be used, but there is a class of cases in which the use of pessaries is improper As regards the frequency of pelvic inflammation, he believed that it was less common abroad than in America Our young women go into society earlier and they contract pelvic inflammation as a result of imprudence in dress He had found the effects of pelvic inflammation more commonly among the unmarried than among the married

DR SAMUEL C BUSEY, of Washington, read a paper on

CYSTOCOLPOCELE COMPLICATING LABOR AND PREGNANCY

This term is applied to the prolapse of the bladder into the vaginal passage The prolapse may be partial or complete It may occur anteriorly or laterally It is well known that distension of the bladder frequently complicates labor, but the subject of cystocolpocele has not received much attention It is a rare accident, and when present often overlooked The author had been able to find six reported cases of cystocolpocele complicating pregnancy Where the distended bladder can be detected externally, there is no difficulty, but where the prolapse is into the vagina, many of the cases are doubtless regarded as cases of threatened abortion The speaker reported the following case occurring in his practice

November 24, 1886, he was called to see a woman in the ninth month of pregnancy It was thought that labor had commenced The pains recurred at short intervals The finger in the vagina at once came in contact with a distended pouch The os could not be felt and no presenting part could be discovered It was learned that no urine had been passed since the previous day With the finger of one hand in the vagina while percussion was made upon the pubes, distinct pulsation was observed It was then concluded that the case was one of distended bladder prolapsed into the vagina The patient was then assisted by the nurse to the commode and passed a large quantity of urine The tumor at once disappeared, the cervix could be reached and labor had not begun In this case vesical tenesmus was not present

Cases of cystocolpocele complicating labor, although rare, are more numerous than cases of the same condition complicating pregnancy The author had found 37 such cases recorded Mistakes in diagnosis have often been made, and on several occasions the bladder has been punctured under the impression that it was the amniotic sac

The condition is usually accompanied with pains somewhat like those of labor, but unaccompanied with any progress towards expulsion of the fœtus In some cases there is complete retention of urine with frequent desire to empty the bladder More frequently there is a scanty discharge of urine with vesical tenesmus If the prolapse is partial and the organ empty, a firm hard mass marked with sugar will be found If the bladder is completely prolapsed and partially or completely filled with urine, there is an absence of vesical intumescence above the pubes and a tumor will be felt in the vagina, completely closing the vaginal canal The finger can be swept over the lateral and posterior portions of the tumor, but not in front Where the prolapse is anterior, labor cannot be completed until the urine is removed The only certain sign of this affection is the discharge of urine through the urethra and the subsidence of the swelling

DR WILLIAM GOODELL, of Philadelphia, had met with two cases of this condition, one a few days before labor and the other during labor In the first case he found a body as large as the child's head and as hard There was severe vesical tenesmus He could not pass the finger behind the tumor and there was no evidence of an os uteri Further examination showed the swelling to be due to the distended bladder A catheter was readily introduced and relieved the swelling There was no return of the trouble The other example of this condition occurred in a case of antero posterior contraction of the pelvis The pain was very great, but the cause of the difficulty was soon recognized It was impossible to introduce either the soft or the metallic catheter He then put on the forceps, and raised the head so that the catheter could be passed in The labor was then completed with the forceps

AFTERNOON SESSION

DR WM M POLK, of New York, read a paper entitled

IS SALPINGITIS TO BE TREATED BY EXTIRPATION OF THE TUBES AND OVARIES IN ALL CASES?

By salpingitis the speaker meant that disorder whose most marked clinical symptom is found in the presence of the peruterine masses so commonly met with in palpating the pelvic contents The most common result of this condition is displacement of the tubes The author had already made a report on 100 cases of salpingitis In 50 of these cases the abdomen was opened and in 50 no section was made, but in these a comparison of the results of careful examination left no doubt that the whole series of 100 cases represented the same disease The majority of cases of salpingitis recover Even where a small quantity of pus is present this may be encapsuled by lymph and do no harm Some of the cases remain as confirmed invalids, while a few die Outside of the puerperal condition the death rate is low, and including antiseptic midwifery the death rate is still low The main symptom observed was dysmenorrhœa

An examination of the cases coming under the author's observation led him to believe that the chief cause of the symptoms in many cases was the presence of adhesions He had operated, removing the adhesions, but allowing the tubes and ovaries to remain, on the ground that although pregnancy might not occur, yet as their removal was unnecessary, mutilation could be avoided and one of the objections to the operation removed The question whether or not the adhesions will reform must be answered by experience The author reported eight cases operated on in this way In one case there was shortened utero sacral ligaments, the posterior face of the uterus touching the rectum The ligament was stretched, a drainage tube inserted and the patient did well She had suffered for a long time from dysmenorrhœa and pain during coition, and other evidences of so called cellulitis or chronic salpingitis In the second case the uterus was retroverted and bound down by adhesions These were torn, the tubes and ovaries loosened and the uterus held forward by Alexander's operation, the object being to displace the uterus from the old position and prevent the formation of new adhesions Within proper limits the extirpation of the uterus and ovaries is a valuable operation It is, however, desirable to confine it within its narrowest limits, and where it is possible to avoid mutilation, to do so

DR A MARTIN, of Berlin, said that progress can only be made in this important matter by distinguishing between the different forms of disease of these organs In only a small number of cases is the tube the seat of a neoplasm He had found only one case of carcinoma of the tube The most frequent disease of the tubes is catarrhal inflammation, extending from the uterus We frequently see it following the puerperal state It has often been supposed that the salpingitis was of gonorrhœal origin, but only in a few instances have the gonococci been found in the tubes In most cases, the disease of the tubes is a benign affection, a catarrh which increases the size of the tube and may give rise to hæmorrhage, particularly at the time of menstruation, and occasionally to pyo salpinx Frequently, early occlusion of the tube is the result

Only a small number of the 250 cases coming under his observation had required operation As in most cases the disease is a simple catarrh, we must first institute treatment adapted to the simple nature of the affection If we do not succeed in relieving the symptoms and reducing the size of the tube, we are to operate He had done eighteen operations for disease of the tube, but very seldom did the tube give him the occasion for the operation Generally it was the spread of the disease to the other pelvic organs, particularly the ovaries In many cases there was abscess of the ovaries This severe complication is not observed with sufficient frequency as to warrant operations in all cases of salpingitis He had lost about 12 per cent He never performs the operation except where there is a distinct tumor In nearly all of these cases there was severe peritonitis In the majority of cases we can cure these patients by general treatment

DR T A EMMET, of New York, held much the same views as Dr Martin A large number of these cases can be cured by careful general treatment, and it is our duty to operate in no case until the woman has had an opportunity to see whether or not she can get well without operation When the disease of the tube is unquestionably of gonorrhœal origin, the operation may be resorted to at once He was satisfied that two thirds or more of the cases operated on to day, will not be operated on five years from this time

DR WILLIAM GOODELL, of Philadelphia, agreed in a large part with what Dr Martin had said His rule is to try in the majority of cases the effect of rest treatment, with general and local medication It seemed to him that the author of the paper gives us an operation more dangerous than the removal of the ovaries What objection is there after the abdomen is opened to the removal of the ovaries and tubes? This is not a mutilation, they are unable to perform their function Rather than resort to a second operation, such as Alexander's, he favored the removal of the tubes and ovaries In cases of malposition of the uterus, associated with disease of the tubes and ovaries, he had frequently righted the uterus by introducing a pessary at the time the ovaries and tubes have been removed and keeping it in during the process of recovery

DR G BANTOCK, of London, remarked that the question which has been proposed may be answered in the negative Ordinary cases of salpingitis due to catarrh can be cured by rest and constitutional treatment When it comes to pyo salpinx and hæmato salpinx the conditions are different A well marked case of pyo salpinx, whether due to catarrh or to gonorrhœal infection, will require operative treatment He had, however, seen tubes which evidently had contained a large quantity of pus, but which when examined contained only a small quan-

tity of cheesy matter It is rare to have death from the rupture of a pyo salpinx In hæmato salpinx the condition is far more serious than in pyo salpinx

About one year ago, he had under treatment a case of fibroid tumor of the uterus The patient suffered a great deal of pain and he was induced to operate When the brim of the pelvis was reached the adhesions were so numerous that he could not proceed He therefore determined to remove the ovaries and bring about the menopause The left ovary was removed without difficulty, but the right ovary could not be found Fluid was detected in the right side and an incision showed that there was a fibroid tumor which had undergone cystic degeneration The edges of the cavity were stitched to the abdominal wall, a large opening being left to facilitate drainage In three months the patient was quite well She subsequently married and a short time ago was delivered of a living child It is therefore clear that when the mischief arises from the outside of the tube, sterility does not necessarily result When, however, the inflammation begins inside, sterility will probably be induced With reference to the procedure suggested of loosening adhesions and allowing the tubes and ovaries to remain, he was inclined to think that that is not the correct treatment If the tubes and ovaries are so diseased as to require the removal of adhesions, he considers it proper to remove the tubes and ovaries also The effect of applying ligatures on each side of the uterus is to lift the organ into a more satisfactory position than can be done by Alexanders's operation

DR R S SUTTON, of Pittsburg agreed in the view of salpingitis that all cases should not be operated on, but if pus exists in the Fallopian tube it is our duty to evacuate that pus, just as it is our duty to evacuate a collection of pus in the arm No one has a right to allow a woman to go around with a pus sac ready to burst into the peritoneum, when he can remove it The condition of life of the patient must be considered A poor woman may require operation, while a rich one might be able to get along without operative measures

DR GILL WYLIE, of New York, said that in one thousand of his earlier cases of pelvic peritonitis and cellulitis, he operated about once in every ten cases In later years the proportion has increased Of his last sixty cases 60 per cent were for pyosalpinx, and all these cases have recovered He should not be willing to try the operation suggested by the author

DR WM M POLK, of New York, remarked that the question which he had considered was in regard to mutilation A woman has a right to her ovaries if they do her no harm Dr Bantock's case shows that the presence of adhesions is not a bar to pregnancy He thought that the removal of the tubes is a most important operation, but we must avoid extirpation of the tubes and ovaries unnecessarily

DR PAUL F MUNDE, of New York, read a paper on

DRAINAGE AFTER LAPAROTOMY

While drainage is an accepted procedure in general surgery, its position in abdominal surgery is not yet settled The author then quoted the opinions of various operators, showing the great diversity of views If antiseptics can prevent the decomposition of fluids left in the abdominal cavity the use of the tube can be dispensed with So long as there is any doubt as to this, so long, at least theoretically, will drainage be called for Some of the disadvantages connected with the use of the tube are, that the abdominal wound can not be completely closed, the danger of septic contamination through the tube, the liability to ventral hernia is increased, and there may occur serious reflex gastric irritation Whatever good is done by the drainage tube is probably accomplished within the first 24 hours As soon as the fluid which escapes is serous or serou sanguinolent the tube may be removed It has recently been recommended that in cases where it is found impossible to remove the whole tumor and a large cavity is left, a sac of iodoform gauze be made and packed into every crevice of the cavity This is then filled with narrow strips of iodoform gauze This the author had employed with satisfaction At the end of ten days the dressing was perfectly odorless

It was thought that when drainage seemed necessary the tube might be omitted, and the removal of fluids accomplished by an antiseptic gauze strip passed through the vaginal roof into the vagina This permits of the perfect closure of the abdominal incision

DR A MARTIN, of Berlin, does not employ drainage after ovariotomy, for the absorbing power of the peritoneum is so great that it can dispose of a considerable quantity of fluid He uses drainage in only a few conditions He uses it in amputation of the uterus through its neck, in vaginal hysterectomy, and where there are large surfaces of a sloughing character and large cavities left in the broad ligaments, as in extra uterine pregnancy, in large fibroid tumors which have been enucleated, and in large cystic tumors where all the surfaces can not be brought in contact In these cases he uses the drainage-tube passed through Douglass' cul de sac into the vagina

DR G BANTOCK, of London, said that so confident was he of the value of drainage that he uses it on the slightest provocation He uses it where there has been abundant adhesions and where it has been found impossible to completely dry the peritoneal cavity He uses it where the tumor has burst and it is impossible to remove all the contents In these cases he uses also large quantities of clean warm water He has given up everything in the form of antiseptics Since then his results have correspondingly improved In his last 104 ovariotomies he had lost three, and in the last 78 he had not lost one While he values the use of the tube, he did not think it was required in the majority of cases of ovariotomy He employs the ordinary straight drainage-tube introduced to the bottom of the wound It should be emptied every two or three hours This prevents any absorption of the effused fluids and the patient recovers without any elevation of temperature or any alteration in the pulse When the fluid

removed is nothing but plain serum, the tube may be taken away, but if it is removed before all blood has disappeared great risk is run

Dr Gill Wylie remarked that one of the advantages of the use of the tube has not been referred to, and that is that it gives us early information as to the occurrence of hæmorrhage

Dr Wm Goodell, of Philadelphia, said that he was not a believer in the drainage-tube, although he used it occasionally In three or four cases he had colloid cysts rupture three or four weeks before operation, and when the abdomen has been opened all the organs have been found covered with the colloid material These cases recovered without the use of the drainage-tube This was before the time of washing out of the abdomen In a recent case of the same kind he used a drainage tube, and not more than three ounces of fluid escaped He agreed with reference to the great value of the tube as showing the presence of hæmorrhage In one case a fæcal fistula occurred, and this he attributed to the presence of the tube

(To be concluded)

SUFFOLK DISTRICT MEDICAL SOCIETY

Section for Clinical Medicine, Pathology and Hygiene

Stated Meeting, May 11, 1887

Dr F I Knight, Chairman

Albert N Blodgett, M D, Secretary

(Concluded from page 476)

Dr F I Knight read a paper on

the contagiousness of tubercular disease of the lungs, with a report of one case

In July, 1885, a young lady of 19, came to my office with a history of cough of nine months duration I found signs of phthisis in one lung Her father was a very strong man, her mother had died of some nervous trouble after child birth There had been ten children, five of whom died in infancy, none of them with any brain or lung disease There had been also six half brothers and sisters, one of whom had died in infancy Of the uncles and aunts on both sides, only one uncle had died of phthisis The patient gradually declined, and died April 15, 1887 She was accompanied in her visits to my office by an older sister, 23 years of age, who had given up everything to attend to her This sister, while not robust looking appeared well, and said that she had always been so She occupied the same room and bed with her sister This I protested against, and advised her to go out regularly every day for walks in the fresh air The last record made of their visits to me was in the latter part of October, when the phthisical patient became too sick to come to me, and went under the care of her family physician in a neighboring city, she died, as I said, on the 15th of April On the 19th of April the sister came into my office with the following history She had continued to attend closely upon the invalid all winter, and had disregarded all my advice She had even slept with her sister up to within five weeks of her death She was with her night and day During the latter part of her sister's life her breath was so offensive that she could eat almost nothing, and only kept herself up by the free use of stimulants She stated that she had had a little dry, hacking cough for a month She breathed rapidly, but said there was no dyspnœa On examination her pulse was found to be 140 Temperature 104° On examination of the chest, subcrepitant rales were heard in both upper lobes, front and back, and the diagnosis of acute pulmonary tuberculosis was made Examinations, April 26 and May 3 confirmed the diagnosis On the 21st of May, she came to my office so weak that she had to be assisted from the carriage to the house She reported hæmoptysis of several months two weeks before She was so weak that I did not examine her chest Pulse, 160, temperature, 103 4° I did not see her again, and she died June 17, 1886, about two months after I first examined her, and three months after the beginning of the dry cough

Who can fail to believe that the disease and death of this patient was caused by attendance upon her sister? Hardly any one will deny this Admitting it, would she have succumbed to acute *pulmonary tuberculosis*, if she attended upon a sister ill with some other disease? As she had no such hereditary tendency I do not think so How often do we see patients worn out with much longer attendance upon the sick, and yet do not become tuberculous! And how often do we see strong women without the slightest herditary tendency succumb to attendance upon tuberculous patients

It is useless to allege in this connection, that ordinary attendance upon the sick in consumptive hospitals does not affect the attendants I admit this fact, but the attendance is not so prolonged, nor so close as in families Let any one who has doubt about the clinical evidence bearing upon this point read the little brochure of Webb The fact is that tuberculosis is so common with us, that we have almost ceased looking for the immediate cause in any case, especially if relationship gives us a chance to attach the blame to heredity I believe, however, that there are hundreds who have by inheritance that peculiarity of pulmonary soil which favors the development of the tubercular disease Who would not shun it unless they were brought into contact with those already affected? Whether all cases require such a transmission of germs we do not know

In what manner is it probable that the disease is communicated? It has been claimed that bacilli have been found in the breath, but it is, perhaps, more probable that the communication in most cases is by dried sputum, which becomes diffused in the atmosphere We have abundant proof that tuberculosis can be readily communicated to animals little liable to it, for example dogs, by causing them to inhale for an hour or two a day an atomized solution of the sputa of tuberculous patients (See

the experiments of Tappeiner and others in substantiation of this statement)

So then, I say that the appearance of tuberculosis of the lungs in countries where it was previously unknown, with the ingress of people from countries where it was common, the marked increase in the disease in the neighborhood of health stations resorted to by the tuberculous, the personal history of the development of cases in our midst, and experimental work with the sputa, all point strongly to the probable communication of the disease under favorable conditions, and make it not only incumbent upon us, in case of pulmonary tuberculosis in a family, to establish precautions against communication of the disease, but makes us criminally negligent in failing to do so

What precautions shall we take? These pertain (1) to the patient, (2) to the quarters he occupies, and (3) to the exposed attendant

The patient should be made careful in the disposal of his sputa, either to deposit them in a cup in which some germicide has been placed, or if the patient is feeble and obliged to use cloths let them be destroyed before any drying occurs It would hardly seem to be necessary to warn respectable patients not to spit about them carelessly, yet I have seen with respectable people the most utter indifference in this regard

For disinfection of the spit cups, Dr Ernst informs me that a 5 per cent solution of carbolic acid is the best Corrosive sublimate does not answer, as it coagulates mucin, and does not reach the bacilli at all

In regard to the room we should secure change of air by every known device, and as long as possible by a daily removal of the patient from his room, for the purpose of thorough ventilation Clothing and bed-linen should be frequently changed The absolute value of antiseptic sprays for the room in such cases we know not, and the use of those which are offensive in themselves should not be recommended But such as are pleasant to the patient and attendant would be of service at least in counteracting the disagreeable odor which attends the last stages of pulmonary disease

In regard to the exposed persons, let it be said that from the moment tubercular disease is discovered, another person should not occupy the same bed, not only for the sake of the exposed person, but also that of the patient, who will rest much more comfortably alone Sleeping in the same room should also be forbidden, as we seem to be more susceptible to all infectious diseases during sleep The attendant should have daily exercise in the open air, and if a relative, an occasional complete change, if possible In case of any failure in health, this should be insisted upon, and although the physician cannot always prevent self sacrifice on the part of friends, he can often modify it At any rate, he should not feel that relief of his patient was his only duty, but that his duty extended to the surroundings of his patient, and required that these should be arranged with due regard to the protection of relatives and friends

If there is any decided hereditary tendency to the disease, relatives should if possible, be prevented from any attendance upon the sick, and put at once upon proper hygiene

DR STUART When I was at the Carney Hospital I saw a case of a young lady, she was the step daughter of a consumptive who had just died, the question as to whether her mother died of phthisis could not be brought out The patient did not seem to know She was one of a family of eight brothers and sisters, all well, and she alone had evidence of phthisis According to this patients statement, while her step mother was sick for fourteen months she had hardly been out of the house Dr Devine, in speaking of the case, said he knew of a draw-tender who had buried two wives of phthisis, the draw-tender had the disease of course, himself, and the only conclusion which he could draw from this case was that the draw-tender was out in the open air almost all the time, while his successive wives were shut up in the house, and thus the course of the disease was made quicker for them

DR BLODGETT said that he could not refrain from calling attention to the fact in relation to tuberculosis, which is not sufficiently considered in the treatment of cases of this disease He was happy to observe that the chairman had laid stress upon the same point, which is the eminently infectious nature of tubercular disease There is no doubt that many cases of tuberculosis are communicated from one person to another, but the cases are not followed with that care which is everywhere thought desirable, even imperative, in relation to other infectious and contagious diseases The time has probably not yet arrived when we can test this class of diseases in the manner which would be applicable to other communicable diseases We are too much under the domain of public opinion to venture the rational and only real method of treatment which is directed to the peculiar character of the malady in question We can not properly utilize the knowledge which we already possess in relation to tuberculosis

In some foreign hospitals, patients with tuberculosis are treated in the same manner as are those with other dangerous disorders, that is, the sufferer from tuberculosis is segregated from other patients, and is isolated in a ward devoted to infectious diseases, where he is subjected to a rigid seclusion from the other sick to whom the disease might be communicated Much the same care and seclusion is exercised in relation to tuberculosis as is done with scarlet fever, measles, etc Dr Blodgett said that he had recently had a case under his own care in which the germicide treatment was adopted as one of the principal measures of relief, and in which there was an entire disappearance of all symptoms of disease The patient is the son of a clergyman, and is about 40 years old His father was for many years a sufferer from chronic pulmonary disease, and died after attacks of pulmonary hæmorrhage, presumably of tuberculosis The mother is still living, but has long been in feeble health The patient was never a strong man, but maintained his ordinary standard of health until five years ago, when he was the sub-

ject of fistula of the anus, for which he was under treatment by surgical measures for a year Since that time he has been somewhat feeble, and eighteen months ago he began to fail perceptibly Twelve months ago, he was under treatment for hoarseness, which advanced to a degree which rendered speaking above a whisper almost impossible At this time he came under the care of Dr Blodgett who found distinct ulceration of the larynx, with induration and impaired mobility of the vocal structures, and by microscopic examination the bacillus of tuberculosis was readily demonstrable The patient was at once placed under treatment by means of tonics, removal to the country, the use of antiseptic lotions and inhalations, principally of mercuric bichloride, the employment of which was rendered tolerable by means of antecedent applications of cocaine He passed some months on the sunny side of a hill selected with some care in New Hampshire, and late in the autumn returned to Boston He gave up his previous residence, and removed to the highest part of Newton, into a new house, on sandy and dry soil, where he has since resided He has steadily improved, his weight has increased from 122 pounds to 140 pounds He has never been so heavy as at present He is gaining strength, the voice has returned, and there is every reason for believing that the disease has entirely disappeared

It is true that this was probably not a case of *contagion*, but it is illustrative of the way in which a disease which is contagious should be looked upon It would, in all probability, have been perfectly possible for this patient's wife or child to have acquired the disease, by contagion He had constant attacks of bronchial or pulmonary irritability, frequent catarrhs, and recurrent periods of hoarseness and threatened pulmonary tuberculosis His system furnished a soil which was peculiarly adapted for the reception of such a disease

Dr Harold Williams remarked that when a student he had been taught by Dr Knight that phthisis pulmonalis was communicated by the sick to those in attendance upon them under certain conditions, and that in his practice he had never had occasion to change this view He had not come prepared to cite cases in proof of this doctrine, but could say that he had never doubted its truth, and that he had each year many cases which confirmed it both at the Boston Dispensary and elsewhere The two principal arguments against the view of contagion were *first*, that phthisis was the commonest disease in our community, one fifth of our people dying of it, and that cases of its supposed contagion were cases of coincidence This argument Dr Williams thought could be answered by saying that the reason of its frequency was because of its contagiousness, and the absence of sufficient precaution in protecting the well against the sick The second argument of the immunity of the attendants of phthisical patients in hospitals had been answered by Dr Knight Dr Williams not only believed phthisis to be contagious, but he believed the bacillus to be the element of contagion, and this had suggested to him that the well-known germicide properties of arsenic might account for the efficacy of this drug in phthisis, and that he was conducting some experiments to test this theory Since reading Jaccoud's book, in which the administration of arsenic is highly recommended, Dr Williams had employed it in several cases with good results, especially in one girl with phthisis of three months' standing, in which case its administration had been followed by complete recovery Dr Williams questioned if the good effects so strongly insisted upon by Jaccoud might not be due to the germicide properties of the drug, rather than to its action as a tonic, and as diminishing blood pressure and calming nervous irritability as claimed by Jaccoud

FOREIGN CORRESPONDENCE

LETTER FROM LONDON

(FROM OUR OWN CORRESPONDENT)

Ulexine—Papaw—Surgery for Nurses—Miner's Nystagmus—Funnel end Œsophageal Tubes—Prescription for Hay Fever and Summer Catarrh—Turpentine in Headache

With a degree of unconventional boldness which some will characterize as bordering upon audacity Mr E Harry Fenwick, the well known specialist in diseases of the urinary system, treated the students of St Peter's Hospital at a recent lecture, to a discourse of a very different kind to the ordinary run of "hospital lectures" The lecture in question included a succinct description of the more important properties of cocaine, kava kava, strophanthus, salix nigra, pinus sylvestris, lycopodium, etc, which Mr Fenwick has found exhibited by the respective drugs in his own actual practice The lecturer commenced by referring to the changes which had been introduced into our therapeutical practice of late years, and pointed out how much more had been done on the Continent than in England, although here we were in some respects well situated for obtaining raw material to work with, and also for the means of experimental study Mr Harry Fenwick concluded with a few remarks upon ulexine extracted by Gerard from the tops of the common furze or gorse, (ulex Europæns,) describing it as a strong respiratory poison Crucial experiments upon frogs shows that ulexine powerfully excites the urinary secretion, but the effect is transient Thus where the normal flow was three drops per minute but after two minutes this quickly retrograded to its original amount Somewhat similar effects were noted in the human subject, and it had been given with advantage in some instances, but in cases of long standing stricture of the urethra, doses of one-tenth grain had induced severe vomiting, with much pain, blackening of the tongue and other inconveniences, hence ulexine needed to be administered with caution With regard to papaw (carica papaya), the lecturer had successfully applied it for the softening and removing of diphtheritic membranes at the London Hospital, and he had found it of marvelous power in dislodging and bringing away renal stone, the pain being relieved in a very short time Papaaine was also used by him with advan-

tage in cases of dyspepsia, and in India it was employed as a remedy for tape worm, as it not only killed them more certainly than the oil of male fern but quickly dislodged and partly dissolved them

A small work by Mr Joseph Bell, dedicated to Florence Nightingale, and called "Notes on Surgery for Nurses," is quickly running through its first edition The author, who has for twelve years delivered lectures to the nursing staff of the Royal Infirmary at Edinburg, now publishes the pith of them in a concise form, which should be of service to those for whose benefit the lectures are intended The subjects dealt with include nearly all of those diseases in which the nurse plays an important part, and her duties in each case are fully explained In speaking of the necessity of cleanliness in all cases of ulceration the writer remarks "Ventilation of wards, cleanliness of floors, walls and bed linen, have helped, and it is now nearly a quarter of a century since I have seen a case of hospital gangrene"

Dr Charles Taylor of the Nottingham Eye Infirmary, speaking of miner's nystagmus, says that he does not consider it to be caused by, or accompanied with any lesion of the central nervous system, but in pure myopathy, analogous to that rare condition of the muscles of articulation known as auctioneers' spasm, or to writers', pianists' and telegraphists' cramp, or to similar affection of the gastrocenemic muscles occasionally observed in ballet dancers, who run on tiptoe until they are attacked by cramp, spasm and uncontrollable motions whenever they attempt to dance at all The extraordinary oscillation of the eyeball noticed in the subjects of nystagmus he considers to be due to the close connection which exists between the ciliary muscle and the internal rectus, may be developed in any muscles engaged in the effort at accommodation and is caused solely by the overtaxing of these organs The miner, surrounded by black objects, makes day after day, for years, a great and sustained effort to see in an imperfect light (especially imperfect when safety lamps are used) The muscles engaged in this continued strain are overtaxed, and in course of time give way, and at last, when called upon, become agitated and fluttered, escape from control of the will, and just as in the analogous case cited above perform irregular motions, so that, as miners express it "the lights dance," whenever they look at them

Mr Charters Symonds' short funnel ended tubes for wearing in the œsophagus in cases of cancerous growth, stricture, etc, have recently been used and found most successful in some of the London hospitals These are a great improvement on the old long tubes hanging out of the mouth, as they allow of the food being taken in the natural way, instead of the unpleasant mode of feeding by means of the funnel

Sufferers from hay fever and summer catarrh should make a note of the following recipe, given by Mr Martindale, of New Cavendish street, for smelling salts calculated to relieve these affections Absolute phenol 24 grains, carbonate of ammonia 16 grains, strong solution of ammonia 44 grains, oil of lavender 1½ grains, camphor 3 grains, pure sawdust 9 grains The author of the prescription speaks highly of the results he has obtained amongst his clients who have used it during the past summer

Turpentine in doses of 20 or 30 minims, it is said, will not only remove headache, but produce in a wonderful manner a soothing influence

DOMESTIC CORRESPONDENCE

STATEMENT OF THE SECRETARY-GENERAL IN RELATION TO THE MATTER OF ITALIAN DELEGATES AT THE INTERNATIONAL MEDICAL CONGRESS

On the 9th of November, 1886, I addressed a letter to Professor Mariano Semmola, of the University of Naples, requesting him to be present at the Congress, notifying him of his election as Vice-President, and asking him to deliver an address at the general session In response to this, Professor Semmola in accepting the invitation, replied under date of the 26th of November, 1886, as follows

NAPLES, November 26, 1886

Monsieur et tres honore Confrere

Je m'empresse de vous repondre par le retour du courier à votre aimable lettre du 9 courant Je vous remercie de l'honneur que vous me faites en m'appelant a une conference meeting et j'accepte bien volontiers cette charge Le subjet que je traiterai dans cette conference generale est le suivant La bacteriologie et la clinique therapeutique

Je vous prie en même temps de vouloir m'inscrire dans la Section de Medecine pour les travaux suivants

1 Nouvelles preuves experimentales et cliniques de l'origine dyscrosique de la Maladie de Bright

2 De l'ataxie paralytique du coeur d'origine bolboire

3 Contributions à la pathologie du sympathique

S'il le faudra j'aurai l'honneur d'envoyer au Secretariat general le resume ou les conclusions principales de ces travaux J'attends à ce propos des renseignements que vous pourriez avoir la bonte de me donner Veuillez agreer l'assurance de ma haute consideration Tres devoue,

[Signed] M SEMMOLA

He was therefore inscribed on the Register as a member of the Congress, and when the programme was issued, duly reported thereon as one of the gentlemen named to deliver a general address

On the 6th of June, following, the Baron Fava, the Italian Minister to Washington, addressed the following letter to Dr Dunglison, the Secretary of the Executive Committee

ITALIAN LEGATION, WASHINGTON, June 6th, 1887

Dear Sir—In reply to your esteemed favor of the 31st August last I beg to inform you that my government has appointed as its official delegates to attend the *Ninth* International Medical Congress, to be held in Washington in September next, the following gentlemen

Comm Professor Mariano Semmola, Senator of the Kingdom of Italy, and Dr Francesco Durante, Professor of the surgical clinic at the University of Rome

Believe me dear sir, with the best regards,

Very respectfully yours

[Signed] BARON FAVA
Italian Minister

As the letter was addressed to him, Dr Dunglison did not send the letter to me, but retained it until two days before the meeting of the Congress

On Saturday before the meeting, the question of preparing the preliminary programme was discussed

by the President of the Congress, the Chairman of the Executive Committee, and myself, and the programme was then prepared As there were two delegates from Italy it was concluded that, as Professor Semmola was to have the general address—considered by us all as one of the honors of the Congress—that the other delegate should be selected to deliver the address on behalf of Italy, in response to the speech of welcome of the Honorable T F Bayard, Secretary of State of the United States I verbally communicated this desire to Professor Durante on Wednesday evening, to which he assented as follows

RIGGS HOUSE, August 31, 1887

DR HAMILTON, S G U S M H S

Dear Sir —In response to your courteous invitation that I as the Representative of the Italian Government should answer the address of the Secretary of State of the U S have the honor to say that I accept with pleasure Respectfully,

[Signed,] FRANCESCO DURANTE

Professor Semmola had not up to this time arrived in Washington The morning papers of the following date contained a notice that Professor Durante had been so requested, and Professor Semmola, arriving in Washington on Sunday, he, with his Secretary called on me, in my office at the Riggs House, and stated that he, being a Senator of the Kingdom of Italy, felt it was his privilege to reply in an address of semi official character, and his Secretary stated to me that, if the demand were not complied with, Professor Semmola would withdraw from the Congress, and decline to deliver his address I immediately communicated with President Davis, and others of the Executive Committee, and it was decided that, as his claim seemed to be sustained by the wording of the letter of Baron Fava, that the programme could not be interfered with by declining to yield to Professor Semmola, and as it would materially interfere with the work of the Congress, and greatly embarrass the proceedings, I sought Professor Durante to explain to him that his invitation had been premature, and that the necessity of the case required that the Committee withdraw the verbal invitation tendered him to respond on behalf of Italy I was unable to find him on Sunday, or Sunday evening In the meantime Professor Semmola was informed that the Committee acceded to his request, and the following letter from him was received

WASHINGTON, September 5, 1887

Monsieur le Secretaire Général

Je viens vous remercier pour la justice que vous m'avez rendue et je garderai comme un des plus chers souvenirs de ma vie publique l'aimable mot que vous avez bien voulu m'addresser

Je vous prie Monsieur le Général, de vouloir faire inscrire mon nom parmi les members du Congrès, aussi bien que les noms de mes deux Secretaries Mr Robert O Wickersham et Monsieur le Marquis Lanza

Je vous prie d'agréer mes sinceres expressions de devoument

[Signed,] PROF M SEMMOLA

Professor Durante, unfortunately, was not communicated with till the next morning, when he appeared in my office I stated to him, and his Secretary, Dr Tricomi, in substance, as follows

Professor Francesco Durante, etc

My Dear Sir —When I asked you on yesterday to make for us a short reply to the address of welcome by our Hon Mr Bayard, Secretary of State, I was unaware at that time that my Senator from Italy was present It seems that Professor Semmola of your great country is also a Senator, and as such he desires to respond on behalf of the country It appears that the precedents of other Congresses be in this direction Thus at the International Anthropological Congress, at Lisbon, Senators Gozzadini and Mantegazza were called upon in a similar capacity Therefore we are under the necessity of extending this Senatorial privilege to Professor Semmola

They withdrew from the room, and I received the following letter

RIGGS HOUSE, September 5, 1887

General Secretary of the Medical Congress

Sir —Having been invited by the Secretary General of the Medical Congress, Surgeon General Hamilton, to answer in the name of my country the address of the Secretary of State, I accepted with pleasure and so informed by letter the Secretary General My surprise was therefore great and painful when this morning while inquiring about the order of exercises at the opening of the Congress the same Surgeon General Hamilton informed me that he had requested Dr Semmola, of Naples, to make the answer This change was done without my knowledge and consent and was therefore an insult

I am the Representative of the Italian Government inasmuch as I was so delegated by the Minister of Public Instructions, the only Minister that has authority to make such an appointment Professor Semmola's appointment is not from the Government but from one Minister, that of the Interior, as an expression of personal regard The plea that Dr Semmola is a Senator of the Kingdom should not be considered in this matter, as this is a medical and not a political Congress In view of the foregoing and of the personal affront, I hereby withdraw from the Medical Congress aforesaid Respectfully,

[Signed,] PROF FRANCESCO DURANTE

This letter was simultaneously published in the daily press of the city

I was then called upon by Dr T S Verdi, of this city, who inquired into the circumstances, to whom I related the foregoing, as nearly as possible He then retired, and in the meantime returned saying he had seen Professor Durante and thought the matter could be explained satisfactorily if I would sign a letter, which he produced, and which appears on the first page of *Il Progresso Italo-Americano*, New York, September, 10, 1887 I did not sign the memorandum which he presented to me as appears in this paper, but re wrote it The words as translated in *The Progresso*, are as follows "Grandamente mi dolgo che ho ceduto alla domanda del Prof Semmola e spero che Ella, come Vice Presidente del Congresso, vorrà continuare ad aiutarci col suo consiglio e conla sua esperienza, rimendo con noi," were not used by me, but I said I greatly regret the *circumstances*, etc , meaning thereby that I regretted any controversy should have arisen, as the Committee only desired to promote harmony in the Congress and between the delegates He then demanded of me, through Professor Verdi, that I should say to him exactly what had been said by Professor Semmola that induced the Committee to change the invitation to Professor Durante, which I did in a letter which is probably correctly translated in the paper of the name and date as above given

No disrespect was intended to either of the delegates to the Congress at any stage of the proceedings, and, in regard to the address of Professor Semmola, the Committee were abundantly satisfied and delighted with both the subject matter of the address

and the manner in which it was delivered, and in yielding to Professor Semmola's request to deliver the address of welcome to the Secretary of State they simply desired to carry out the proprieties of the occasion, and to compliment Italy If, however, any injustice has been done any individual, or ill feeling has resulted, they are sincerely sorry, and can only regret the circumstance

Sec -Gen'l International Medical Congress

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

Annual Meeting of New York State Medical Association—Discussions on the Management of Compound Dislocations of the Ankle-Joint—The Origin, Nature, Complications, Sequelæ and Treatment of Typhoid Fever, etc —Opening of the College of Physicians and Surgeons of New York, in the New Building

The last week in September was a very busy and pleasant one in the medical world of New York The fourth annual meeting of the State Association was held on the 27th, 28th and 29th, at the Hotel Brunswick, Madison Square, which proved a much more comfortable and attractive place for the purpose than the somewhat lugubrious and dreary Lyric Hall, on Sixth Avenue, where the Association met last year The attendance was good, and the proceedings characterized by much interest The distinctive feature of devoting the greater part of the afternoon sessions to set discussions on topics of general medical and surgical importance, which has proved so useful and attractive in the past, was retained with admirable results the present session, and the subject of the first day's discussion was the management of compound dislocations of the ankle-joint, which was opened by the distinguished surgeon, Dr Edward M Moore, of Rochester, the last President of the Association, and participated in by Drs Joseph D Bryant and Frederic S Dennis, of this city, U C Lynde, of Buffalo, Frederick Hyde, of the University of Syracuse, and Charles W Brown, of Elmira The second day's discussion was on the origin, nature, complications, sequelæ and treatment of typhoid fever, which was opened by the accomplished and erudite Dr Alfred L Carroll, of Staten Island, recently Secretary of the State Board of Health, and participated in by Professor Edward G Janeway, of Bellevue, Hermann M Biggs, of the Carnegie Laboratory, E D Ferguson, Secretary of the Association, Charles A Leale, ex-President of the New York County Medical Association, and others The special question, "Is there a disease of the lower animals transmissible to man as typhoid fever?" was discussed by D E Salmon, D V S, of Washington, D C, R S Huidekoper, of Philadelphia, and James Law, F R V S, of Tompkins County, New York The third and last day's discussion, on placenta prævia, was opened by Dr George Tucker Harrison, for many years one of the well-known surgeons of the Woman's Hospital, and participated in by Dr Isaac E Taylor, President of the Association, Professors T Gaillard Thomas and William T Lusk, Drs John Shrady, of New York, Darwin Colvin, of Wayne County, William H Robb, of Montgomery County, and others On the evening of September 28 demonstrations in pathology were given at the Carnegie Laboratory, under the direction of Professor Janeway, and on that of the 29th the annual banquet was held

On the 29th of September the new buildings of the College of Physicians and Surgeons were inaugurated with appropriate ceremonies They are situated on West Fifty ninth street, just opposite the Roosevelt Hospital, and are, of course, models of convenience and equipped with all the most approved appliances for the successful study of both the science and the art of medicine The college proper consists of a southern wing, measuring 140 by 43 feet, along Fifty-ninth street, a northern wing, 76 by 43 feet, along Sixtieth Street, and a middle portion, 96 by 55 feet, connecting the other two The southern wing contains the administrative department, with conversation, reading, working, and "bone" rooms On the second and third floors are the museum, professors' recitation and demonstration rooms, the physiological laboratories, and the Swift Physiological Cabinet The top floor, lighted entirely from above, is devoted wholly to work upon the cadaver The main featurre is the public dissecting-room, lighted in the evening by the electric light, and containing 36 tables, at which 180 students can dissect at once About this room are grouped smaller apartments for private dissection, for the teaching of operative surgery upon the cadaver, and for the preparation of material to illustrate the lectures on anatomy and surgery The northern portion of the building is nearly all devoted to laboratories of various kinds, and in the middle building are the two large lecture rooms of the College, one of which will accommodate 450 students, and the other, the amphitheatre, more than 450 students The remaining space is taken up with work-rooms in the various departments

The Vanderbilt Clinic, at Sixtieth street and Tenth avenue, is connected with the College building by a covered passage-way It was built, and the site provided, by the sons of the late Mr Vanderbilt, as a memorial of their father, and in it is afforded a fully equipped dispensary service for the sick poor It contains also a theatre for clinical lectures and small rooms for instruction and physical examinations The Sloane Maternity Hospital is at Fifty-ninth street and Tenth avenue, and provides ample facilities for the practical study of obstetrics It is a lying-in hospital, with 30 beds, given by Wm D Sloane, whose wife, a daughter of Wm H Vanderbilt, has made its beds free in perpetuity

The inauguration exercises took place in one of the large lecture-rooms, and when they were about to commence the President, Board of Trustees, and Faculty marched down the aisle and took seats on the platform The Vanderbilt family was represented by Messrs Cornelius and George Vanderbilt, and among the distinguished men present, not belonging to the medical profession, were President Barnard, of Columbia College, President Gilman, of

the Johns Hopkins University, Professor Dwight, of the Columbia Law School, Judge Gilbert M Speir, and the Hon Chauncey M Depew After prayer by the Rev Dr Weston, Chaplain of the College, the President, Dr John C Dalton, delivered an address mainly devoted to the past history of the College of Physicians and Surgeons, which was founded in 1807, with Nicholas Romeyn as its first President The first lectures were given in a building on what is now Park Place, and it was not until fifty years after it had been started that the institution became the medical department of Columbia College

The inaugural address was to have been delivered by Joseph H Choate, Esq , of the Board of Trustees, but, owing to illness in his family, he was unable to be present, and his place was taken by Prof Wm H Draper, who also presented a large bust of Wm H Vanderbilt, the gift of the Trustees and Faculty, and busts of the late Drs Hosack and Mitchell, and Dr John C Dalton, the present President of the College

In the evening a festival alumni dinner in honor of the inauguration was held at Delmonico's, at which were present about 200 medical men On this occasion Dr C R. Agnew, who is one of the Board of Trustees, presided, and speeches were made by Chauncey M Depew, Cornelius Vanderbilt, the Rev Dr John Hall, Dr William Pepper, Provost of the University of Pennsylvania, and others

The community was recently somewhat startled by the arrival at this port of a steamship from Naples with 8 cases of Asiatic cholera on board, and on which 8 other persons had died of the disease during the voyage The proper measures were at once taken by the quarantine authorities, however, and there is little likelihood of the cholera's gaining a foothold in the city The 8 patients were transported to the hospital on Swinburne Island, where 2 of them subsequently died, and the remaining passengers were taken to Hoffman Island, where they will be retained until all danger of their communicating the disease is over Since their removal to the island two or three other cases have developed among them

P B P

THE FAUCIAL METHOD OF INTRODUCING THE EUSTACHIAN CATHETER

Dear Sir —Catheterization of the Eustachian tube, which occupies so prominent a place in diagnosis and treatment of the diseases of the ear, when attempted in the ordinary way, is not always as satisfactory as the simplicity of the maneuver would indicate

Recently, in the case of an adult who sought relief for distressing tinnitus with deafness, the deflection of the septum was such that the route by the floor of the nostril proved quite painful, and finally unsuccessful, from the fact that she felt the column of air arrested before it reached the middle ear The use of the Politzer bag not furnishing better results, it occurred to me that with the aid of the rhinoscopic mirror and giving the catheter a sufficient curve, I could succeed by the direction of the fauces

The method proved satisfactory and is not painful I found it also available on account of excessive sensibility in cases of rhinitis with deafness It is not so ready a method as that by the nose in patients that present themselves for the first time, but it would seem to have a useful place

In looking over the available literature, I found that Dr Buck alludes to Dr Pomeroy's faucial Eustachian Catheter, and disapproves of its employment without giving reasons Dr Buck's work, Wood's Library Series, bears the date of 1880, a date, prior, I think, to the present extended employment of cocaine, the local use of which obviates reflex spasm and undue sensibility, conditions that would otherwise be in the way of its employment

CHARLES ENFIELD, M D

Jefferson, In , Oct 4, 1887

PUBIC DISLOCATION OF THIGH, With Fracture of Rim of Acetabulum

Sir —June 9, 1887, J D 's horse while in full speed fell on bridge, dragging J D 20 feet with right hip and leg under the horse I found outward dislocation of patella and pubic dislocation of thigh, accomplished reduction with distinct crepitus While waiting for subsidence of effects of chloroform the limb became dislocated by muscular contraction into thyroid foraman, replaced again, after remaining in place few minutes became displaced again This was repeated several times Finally retained it in place by pelvic bandage and compresses anterior and posterior to great trochanter Bandage removed July 1 On July 10, through severe muscular spasm, thigh became dislocated again Dr C S W and myself succeeded in accomplishing the reduction with same result as in the former reduction, finally retaining it in place with the bandage and compresses July 11, excessive vomiting and depression set in, with paralysis of left arm and right foot, with paralysis of sensation along entire extent of external popliteal nerve Under use of arsenic and electricity arm and leg recovered, foot remains permanently paralyzed Passive motion of hip is gradually restoring its function Length of limbs equal

NECROLOGY.

WILLIAM A BYRD, M D

The Adams County Medical Society places this minute upon its records in memory of Dr William A Byrd deceased August 14, 1887 Dr Byrd was born in Both Co , Va , in 1843 Graduating at the Missouri Medical College in February, 1867, his professional career covered a period of just twenty years, eighteen of which he was a member of this Society He was a student of untiring industry and large capacity for endurance, and gave himself unsparingly and with real enthusiasm to the work of

his profession With a natural aptitude for surgery he early devoted himself especially to that branch, and became noted for his boldness, operative skill and fertility of resource

The publication of improved methods and devices adopted by him in operations upon the colon, and on the use of wire in ununited fractures, but especially the former, attracted wide attention, gained him recognition in the American Medical Association, and gave him honorable standing in the International Medical Congress at its meeting in London In the year 1885–6 he was president of the Illinois State Medical Society Dr Byrd became a member of the Adams County Medical Society in May, 1869, was elected president in 1874 and again in 1877 The period of his membership in this society corresponds to its busiest and most fruitful years, and we recognize the fact that for this fruitful activity much is due, not only to the large part personally borne by Dr Byrd in its professional work, but to the stimulating influence of his example upon his fellows C W R

JONATHAN LEONARD, M D

Jonathan Leonard, M D, was born in Sandwich, Mass, January 7, 1805, and died at his home in Sandwich January 29, 1882 His father, Dr Jonathan Leonard, was a physician of long and successful practice, and the son early became interested in the science of medicine He graduated from the Harvard Medical School in 1828, and soon after commenced practice with his father He removed to Boston in 1836 Notwithstanding the advantages of the city, a life in the country was more congenial to his tastes, a love of nature being a strong element of his character, and in a few years he returned to Sandwich for the remainder of his life-work Dr Leonard became a member of the Massachusetts Medical Society in 1831 A close student, and thoroughly devoted to his profession, he soon became widely known as a skilful physician and a wise counselor in all difficult cases His good judgment, delicacy and gentlemanly bearing, made him invaluable in his profession and gave him the confidence of the community He joined the American Medical Association in 1849 He was thoroughly good in his life, pure in his motives, refined in his tastes, tender sympathies, and charitable in his judgment He was deeply interested in all that pertained to the welfare of his native town, particularly its educational interests In his religious views he was broad and liberal, was always a generous contributor to that branch of the Christian Church whose teachings were in harmony with his own thought His last illness was extremely painful, but retaining his consciousness to the last, he bore his sufferings with fortitude and implicit trust in God He was married twice, December 31, 1834, to Alice C Babcock, daughter of Samuel H Babcock, of Boston, and March 31, 1878, to Mrs Mary T Jarvis, daughter of C C P Waterman, of Sandwich, who, with a daughter by the first marriage and a son by the second, resides upon the old homestead in Sandwich

RUPTURE OF THE UTERUS

Read before the Section on Obstetrics and Gynecology, at the Thirty eighth Annual Meeting of the American Medical Association, June, 1887

BY WM H WATHEN, M D,

OF LOUISVILLE PROFESSOR OF OBSTETRICS AND DISEASES OF WOMEN IN THE KENTUCKY SCHOOL OF MEDICINE EX PRESIDENT OF KENTUCKY STATE MEDICAL SOCIETY CONSULTING GYNECOLOGIST TO THE LOUISVILLE CITY HOSPITAL, ETC

The uterus ruptures only once in three or four thousand cases of labor, and many physicians of large experience have never seen a case, but it is so fatal in its results, that all cases, successful or otherwise, should be reported to enable us to form more accurate conclusions as to the best means of preventing the injury, or of saving the life of the woman after it has occurred

Rupture of the uterus cannot always be anticipated, but in pelvic deformities, or unusual obstructions to natural delivery, as pelvic or uterine tumors, rigidity of the os, bands in the vagina, hydrocephalus of the child, and malpositions and deformities of the child, or in inordinate uterine action, cicatrices in the uterus from former wounds, and in previous disease or weakening of the walls, there is danger of rupture, which may be prevented But the time allotted me will not admit of an extended notice of this subject in detail, so I must confine myself to the report of an interesting and fatal case that recently came under my observation, and conclude with a few suggestions as to the proper treatment when the uterus is ruptured On Saturday, February 19, at 2 30 P M, I was called in consultation with Drs McDermott and Roberts to a Mrs Mack in her tenth labor, with the following history 35 years old, had always enjoyed good health, had been married fifteen years, and had given birth to nine living children without complications or difficulty At 9 P M Friday, February 11, she felt feeble labor pains and sent for a midwife The pains continued at long intervals until next morning, when the membranes ruptured and contractions stopped She continued to go about and to manage her domestic affairs until 9 P M, February 18, when she began to have feeble pains, but did not send for a doctor or midwife At 11 P M her husband retired and heard no complaint from his wife until 12 30 A M February 19 She called for assistance, but did not appear to be suffering intense pain Uterine contractions immediately ceased, and when the doctor reached her an hour later she was in profound collapse, nearly pulseless, with limbs cold to the trunk In an examination at 2 30 A M, I found the fœtal head lying loosely at the pelvic brim, with the body in the abdominal cavity, and the uterus contracted down to the right inguinal region The limbs were distinctly felt through the abdominal walls Bleeding had ceased, and there did not appear to be much blood in the peritoneal cavity Her condition precluded the possibility of immediate delivery, and her husband would not consent to any operation until he could consult her spiritual advisor We gave stimulants and applied several jugs of hot water about the woman We left her at 4 30 A M with instructions to call us immediately, if any improvement was noticed We did not expect her to live long, and were not a little surprised at 7 A M to find her improved, pulse better, and getting warm We suggested abdominal section, but were told that her husband, who had gone for a minister, had left positive instructions that no operation should be performed in his absence He did not return for an hour, and then her condition was as bad as when I first saw her

With a desire that the woman should not die undelivered, we finally got consent to remove the child *per vias naturales* Having given her ether and whiskey hypodermically, I delivered her with little effort of a dead child, and removed the placenta, without causing further laceration, hæmorrhage or shock After replacing a bunch of intestines that had prolapsed through the rent into the vagina, the laceration was carefully examined It was immediately on the left side of the uterus, extending through the walls from the os externum to the middle of the fundus, splitting the organ half into, leaving the severed edges widely separated The lacerated surfaces were rounded, and there was an absence of physical conditions which characterize rupture in normal uterine tissue, indicating inflammation, ulceration, or fatty degeneration A compress was put on the abdomen, and a binder applied to hold the torn edges together and prevent protrusion of the intestines She died in a few hours, but as a necropsy was not permitted we could not verify the condition of the uterine tissues, though I am sure the laceration was due to some form of metritis, or to fatty degeneration She had taken no ergot, and the contractions were too weak to have ruptured healthy tissues I doubt if we

could have saved the life of this woman by any treatment, but had she been seen immediately after the rupture Porro's operation would have been indicated, for had the torn edges been sutured after Sanger's method union could not have resulted

In view of the recent remarkable achievement in abdominal surgery, and recognizing the almost universal fatality in rupture of the uterus treated by expectancy after the removal of the child by forceps or version, I am surprised to find some well known medical writers and many good practitioners and surgeons, who refuse to recognize abdominal section as the best and safest treatment Of course, the operation is not indicated in incomplete rupture where the peritoneal covering of the uterus is not torn, for in these cases neither blood, bloody serum, or liquor amnii has entered the peritoneal cavity to decompose and cause septicæmia, etc But if the rupture is through the walls, abdominal section is the only rational treatment, and should be done, though the child may not have entered the abdominal cavity, or may have been delivered the operation has few additional dangers, and removes many If the discharges in the peritoneal cavity are carefully removed before decomposition or inflammation, the patient may have no untoward symptom from this cause They may be perfectly wiped away, and the cavities of the abdomen, uterus and vagina may be made aseptic by irrigation with warm antiseptic water

Porro's operation, and the improved Cæsarean section, are the only operations indicated in uterine rupture, the former being preferable in nearly all cases, as it is usually impossible to approximate the torn edges of the rent so as to get perfect union, and if the blood or lochia enter the peritoneal cavity it will cause inflammation and septicæmia, and result in the death of the woman But where the uterine tissue is normal, and the rent even and regular, Sanger's Cæsarean section may be selected Porro's operation is especially indicated in all cases in which there is retention of tissue elements in fatty degeneration due to malnutrition, or in retention of elements or substances that would empoison the blood, such as gangrene, putrid fœtus, etc The success in the improved Cæsarean section where the uterus is not ruptured has been encouraging There are reports of 39 operations with 12 deaths, a mortality of 30 77 per cent If we exclude 5 cases performed as a *dernier ressort* in the United States when the women were exhausted, we have 34 operations, with 27 recoveries and 7 deaths a mortality of 20 59 per cent

In Créde's analysis of 26 cases we have 19 recoveries and 7 deaths, a mortality of 26 67 per cent, but in 3 of these cases septic infection existed before labor, in 2 grave cases it occurred during labor, and in 2 cases the patients died of other complications There are 23 reported operations in Germany and Austria, with 19 recoveries and 4 deaths, a mortality of 17 4 per cent, but not a single death is referable to the operation In 16 operations performed in the Maternity Hospital of Leipsic and the Dresden Maternity Hospital, by Sanger, Oberman, Donát, Leopold and Cohn, there were 15 recoveries and 1 death, a mortality of 6 25 per cent , all the children were saved Lawson Tait proposes to reduce the mortality to 5 per cent in the Porro operation We cannot expect these good results in operations where the uterus is ruptured, but if the woman is not in profound shock, and her condition is relatively good, timely abdominal sections should result in a success of 75 per cent The danger is not so much from the operation itself, the mischief being already done by rending of the uterine tissues and hæmorrhage into the peritoneal cavity, and the profound shock of the nervous system will be exaggerated by further hæmorrhage The operation should be done immediately, for if performed as a *dernier ressort* we must not expect success All the pathological changes are against the late operation, for in the absence of shock, adventitious sacs, plastic adhesions, etc , will have formed, will prove troublesome, and will prevent success

In conclusion, I beg to suggest for your consideration, the substitution of some form of abdominal section for embryotomy in all cases where the child is living I have only alluded in this general way to a few prominent points, hoping to elicit discussion by the members familiar with these questions

DISCUSSION

DR W E CALDWELL, Freeport, Ill In about twenty years I have only lost one patient from this cause This woman had been delivered several times by instruments I was called to her after the membranes had been ruptured for about twelve hours The rupture of the uterus occurred in a few moments after my arrival at the house, and as the woman was *in extremis* I rapidly performed abdominal section with the hope of saving the child, but in that I failed That is all of my experience in regard to rupture of the womb It has been my lot to see Cæsarean section performed six or seven times, and in all of the cases I have seen the women recovered The modern manner of performing the operation is by the entire removal of the uterus I think no good operators at the present day leave the uterus in I think in the case just given, if the doctor had been allowed to operate promptly, he could have done so with a fair prospect of saving the mother, if not the child

DR DELASKIE MILLER, Chicago I desire to ask one or two questions of Professor Wathen before I say anything on the subject I failed to fix the dates of the rupture of the membrane and the rupture of the uterus?

DR WATHEN The membranes ruptured about ten hours after the woman began in labor, and the pains ceased The uterus ruptured about one week subsequent to that date, there were no uterine pains in the interval, nor had she taken ergot or anything of that kind In reply to further questions, Dr Wathen said No one knows the condition of the child during this interval, when I first saw the patient the child was dead and the os was torn entirely through

DR MILLER The case is most interesting, and to my mind illustrates the effect of indecisive action in the management of cases, for want of knowledge

I have no doubt that many cases of rupture of the uterus would occur if cases were left to nature, and assuming, with the author of the paper, that there is a diseased condition of the uterus, this is to be apprehended If there is softening of the wall of the uterus from fatty degeneration or the result of inflammatory action, it is most natural for the wall of the uterus to give way if a limited portion of the organ contracts normally, and rupture will result The point I wish to call attention to is this When labor has commenced and has proceeded so far that the membranes have ruptured, and the contraction of the uterus ceases, it is the duty of the accoucheur to interfere then and assist nature to accomplish the delivery You may say the os uteri is not fully dilated Then it is his duty to dilate it by proper means and effect a delivery I would apprehend in the condition described that there was some abnormal condition present in the seat of the uterus and that some serious complication was to be feared I would anticipate this and effect a delivery Allow me to say what I would do before the rupture takes place, in my own management I not infrequently attend cases of labor where the contractions continue and the patient suffers from severe pain Many times these contractions, although not efficient in inducing dilatation of the os uteri are so severe as to cause the patient agonizing pain These are frequently located in a circumscribed portion of the uterus and I apprehend that some serious complication may be impending When I meet with a case of that kind where the pain is unusually severe I invariably assist nature in effecting a delivery If the inferior segment of the uterus has been dilated and thinned out and the uterus continues to contract actively there is danger of rupture and I would at once adopt measures to produce full and sufficient dilatation of the os uteri and to assist delivery I believe that I have frequently saved patients from this terrible complication of labor by prompt artificial delivery I think the case reported very interesting I am happy to say, since the question has been propounded, that in my individual practice I have never met with a case of rupture of the uterus It has been my fortune to see two cases, which have confirmed the position I have taken, in both cases I believe the rupture was due to delay in active interference If you will allow me a moment I will give in brief the details of a case of a medical man in this city who obtained his medical education in foreign countries, and therefore we would suppose was qualified for the practice In this connection I would say that between the gentleman and myself the warmest feelings of friendship exist This doctor was called at 2 o'clock in the morning to attend a woman in labor He visited the woman immediately and upon examination found the os uteri partially dilated and the uterus contracting regularly, he left her, promising to return in three hours When he returned he found dilatation increased considerably but not quite complete The contractions of the uterus were attended with considerable suffering, but he believed in not interfering too actively in the processes of nature, and left his patient, saying he would come back in two hours, but fifteen minutes before he returned rupture had taken place and the patient was in collapse and did not recover Who does not believe that at his second visit if he had applied the forceps, as he could have done, the patient would have been saved?

DR JOHN MORRIS, Baltimore, Md I have listened to the paper with a great deal of interest I have seen two, perhaps three cases of rupture of the uterus in my experience Dr Wathen says there is great difficulty in the diagnosis There is no doubt great difficulty in foreseeing complications of this kind, but no primipara has ever ruptured the uterus—I do not believe any lady or gentleman in the audience has ever seen, heard or read of a rupture in a primipara It generally occurs in women who have borne eight to ten children If you are called to attend a woman over 40, who has borne eight or nine children, that woman is liable to this trouble If in that labor she has great pain and uses involuntary struggles amounting to violence—for frequently I have seen Irish women do violence to themselves in their effort to expel the child—then interference is necessary You must give large doses of opium and restrain the labor This rarely occurs in women who have had only four or five children In these cases of rupture you are not called upon to make any interference to dilate the uterus, in these women the dilatation takes place very readily and the less interference you make to restrain labor the better That is my experience If you foresee this trouble, apply your forceps if you can Version should never be effected in a woman over 40 years of age, and no man should attempt version if he anticipates rupture of the uterus, he should apply the forceps or perform abdominal section I am convinced that in the case reported if abdominal section had been performed in the beginning that woman would have been saved, because she showed such powers of reaction, the extremities became warm and reaction took place With that reactionary power that the woman could have been saved by abdominal section seems to me the true theory and practice of obstetrics

DR H O MARCY, Boston, Mass It is only within three months that I have seen my first case of rupture of the uterus I will narrate it briefly because I think such cases should be put on record The woman was possibly 35 or 38 years of age, she had had several pregnancies, at the pregnancy prior to the one of which I speak she had lost her child and the physicians told her pretty definitely that she must never have another baby, but did not tell her why The doctor who was in attendance had watched her with care, the labor had gone on to a certain point uninterruptedly The membranes had ruptured—it was a breech presentation—and the breech was well down in the outlet, when suddenly the pain ceased I was sent for in consultation and this was the condition of things when I arrived Delivery was effected without a knowledge of the condition of the parts at the time and the child, which was a very large one, was given to me for resuscitation, which took place The woman was well cared for and everything was supposed to be satisfactory, the placenta came away and the parts were cared for, but within 24 hours

I saw this woman again in a state of collapse, temperature 103°, her pulse could not be counted, respiration about 40, abdomen swollen nearly as large as at delivery The introduction of the hand into the vagina carried two fingers into the retro-uterine pouch, there was a certain amount of prolapse of the intestines and the cavity was filled with clots of blood These were cleansed away and the uterus turned up through the cervix into the pouch of Douglas A long glass tube, such as is used in Vienna, was introduced into the uterus and irrigated very thoroughly with 1 2000 of bichloride of mercury, carried into the uterine rent in the base of the pelvis, and cotton dusted with iodoform was carried up into the vagina From that time she began to rally and at the end of two days was apparently in convalescence The case went on through a slow but very satisfactory convalescence and there can now be seen quite clearly a repair of the rent about 3 inches in length This is the only case I have seen that comes within the limit of the scope of the paper

SYMPATHETIC OPHTHALMIA

Read in the Section on Ophthalmology, Otology and Laryngology, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY C M HOBBY, M D,
OF IOWA CITY, IOWA

The condition to which the term Sympathetic Ophthalmia is applied is well understood, and while the pure pathologist may object to the term, the clinician must still employ it, until a more scientific one is furnished Practically, the name is of little importance, but it is of great importance that we separate the differing conditions grouped under the name For example, ought the so-called sympathetic neuro-retinitis and the occasional lesions of the cornea, following disease or injury of the other eye, to be classed with the inflammations of the uveal tract, that make sympathetic ophthalmia so much to be dreaded?

The object of the present paper is to present the results of observation in a considerable number of cases of sympathetic ophthalmia, sympathetic irritation, and incidentally of severe traumatism My notes cover over 300 cases of traumatism, involving one or more of the tunics of the eye, excluding all cases of superficial injury, and foreign bodies failing to penetrate, from these I have gathered 35 cases, in which injury or disease of one eye has been followed by loss of the other, and in which the lesion of the first eye could rationally be supposed to have a causative relation to the destructive disease of the other Also, 36 cases in which enucleation was performed during sympathetic irritation or sympathetic ophthalmia Also notes of 67 additional preventive enucleations, among which were 5 cases in which trouble followed in the other eye There were 12 cases of enucleation made during panophthalmitis included in the above 67 All of the cases were under observation, at some time during their course, and all but 6 of the enucleations were made by myself

I shall only attempt to analyze these cases in reference to points of practical importance, and must necessarily omit much that would be of interest, especially the results of macroscopic and microscopic examination of enucleated eyes, which has been made in nearly every instance of enucleation during sympathetic ophthalmia or sympathetic irritation

Of the 35 cases in which sight was totally lost by sympathetic disease, 25 were males and 10 females Disease caused 6 cases, 3 males and 3 females, the right eye being primarily affected in 3 cases, the left in 3 Of the cases following traumatism, 29 in number, 22 were males and 7 females, in 17 the right eye was primarily affected, in 12 the left This is in correspondence with the generally recognized fact that males are more exposed to traumatism than females The right eye was the injured one in over 58 per cent of cases, and in general I have found that the right eye suffers more frequently from traumatisms than the left

The time elapsing from injury or loss of one eye by disease, to the occurrence of sympathetic ophthalmia or sympathetic irritation in its fellow, was noted with a reasonable approach to accuracy in 65 cases Of those that are classed as sympathetic ophthalmia, nearly all, probably, had a precedent stage of irritation, but in many the time of occurrence of this could not be ascertained, and the best obtainable data of manifestation of inflammation or failure of vision was used

22 manifested trouble in the second eye in less than a month from the time of injury or loss of vision of one eye by disease (disease playing a small part in these cases), of these 11 developed sympathetic ophthalmia, between 1 and 3 months 7 cases were noted, 4 of whom had sympathetic ophthalmia, between 3 months and 1 year 3 cases, 2 being cases of sympathetic ophthalmia, after 1 year 33 cases, 16 being cases of sympathetic ophthalmia

Weakening of accommodation, intolerance of light, and even hyperæmia of the conjunctival and episcleral vessels, so frequently follows in one eye serious injury of its fellow, that during the first two or three weeks after injury it is often difficult to determine whether sympathetic irritation, in its accepted sense, be present or not I have, however, included only those cases in which relief of pain and irritability of the injured eye was not followed by relief of the irritation of the other

The shortest time I have noted to elapse between injury and well-marked sympathetic ophthalmia was 2 weeks, the longest time 40 years I must, however, confess to some doubt as to the sympathetic nature of 3 cases in which vision began to fail from 20 to 40 years after injury, and in whom there existed no posterior synechiæ

Out of the 35 cases in which vision was lost in both eyes, most of them seen from 1 to 15 years after blindness ensued, the condition of the eye which had been destroyed by sympathetic ophthalmia was as follows In 20 posterior synechiæ, usually complete constituting exclusion of the pupil, were noted, in

2 the globe was atrophic, in 1 absolute glaucoma was the apparent result of traumatism of the other eye, in 1 the results of neuro retinitis were visible, in 3 staphyloma of the ciliary region existed, and in the remainder an opaque cornea, usually vascularized, forbid inspection In reference to sympathetic neuro retinitis I have notes of 5 cases that might be considered sympathetic in their origin, in only 1, however, was the blindness so great as to prevent counting fingers

Sympathetic ophthalmia, following enucleation, I have encountered 5 times

Case 1—J F, male, when seen æt 17, injured at 16 by explosion of gun, both eyes injured, the right hopelessly, the left eye retaining useful vision After 4 weeks, while very painful, the right eye was enucleated, later the left failed very rapidly Examination showed exclusion of pupil, opaque lens, and bare perception of light The only mark of traumatism was a small cicatrix near the lower margin of the cornea

Case 2—W H, male, æt 10 years, had had purulent conjunctivitis in the first year of life, resulting in serious lesion of left eye, which was enucleated, he says, when he was quite small At present the right eye shows occlusion of pupil, bare perception of light, no other lesion discoverable

Case 3—E F G, male, æt 9 Two weeks before he was first seen, he had received a wound from a knife, penetrating the sclerotic, on the inner side of the right eye, involving the posterior part of the ciliary body, for several days he had severe pain, which his physician sought to relieve by the application of bread and milk poultices When seen, the anterior chamber was filled with pus, the conjunctiva was œdematous, and the general appearance indicated panophthalmitis Beyond slight intolerance of light there was no indication of sympathetic irritation The eye was enucleated, the wound healed kindly, and he was allowed to return to his home in a week About one week later I received a letter from his father, stating that he had had severe pain, lasting an hour, over his left eye, and that since that his eye was watering Fearing danger, I telegraphed his father to come at once, and 3 days after the brief attack of pain I saw him The iris was then unyieldingly adherent to the lens, and pushed forward into the anterior chamber in the characteristic manner, from this time the case progressed without interruption to atrophy of the globe

Case 4—F W, male, seen at 60 years of age, the left eye was injured at 53 While the eye was inflamed and painful it was enucleated, shortly after the right eye began to fail When first seen the right eye presented chronic conjunctivitis, vascular pannus slight, anterior chamber shallow, complete posterior synechiæ, opaque lens, quantitative perception of light Vision $= \frac{2}{100}$ was obtained by extensive iridectomy, including all the adhesions, and extraction of the lens

Case 5—R Y, female, æt 53, when first seen had suffered from iritis of left eye, and had nearly complete posterior synechiæ, pupil occluded Iridectomy failed to improve vision, iritis frequently recurred, no view of fundus was ever obtained The right eye was normal The recurrence of iritis ceased, and after 2 months she returned home Warned of the danger to the other eye, and of the advisability of enucleation, during my absence from home 2 months later she visited, at my request, Dr H B Young, at Burlington, Iowa, who enucleated the eye, 2 months later I saw her and found that she was very much impressed with the idea that she was about to lose her other eye I found, however, vision normal, accommodation well performed, and not the slightest indication of trouble I reassured her, as strongly as possible, of safety, and she returned home, 9 months later she returned, with parenchymatous keratitis, increased tension, and several synechiæ From this time the case went rapidly down, exclusion of pupil being followed by infiltration of the cornea with opaque material, and I have since heard ultimate atrophy of globe

In 4 of the 5 cases it is strongly probable that suppurative inflammation of the uveal tract existed at the time of enucleation The former opinion, that suppurative inflammations of the interior of the globe diminished, if they did not entirely remove, the danger of sympathetic ophthalmia, has been recognized as erroneous, and at the last meeting of this Association, the majority of this Section apparently coincided in the opinion that enucleation was indicated during panophthalmitis, not only for the purpose of preventing sympathetic ophthalmia, but to preserve the patient from the suffering incident to prolonged suppuration The opinion was expressed that the risks attending enucleation during panophthalmitis were but little, if any greater than those attending enucleation under other circumstances

While Mauthner confesses that he still stands in awe of von Graefe's advice never to operate if the panophthalmitis be distinctly pronounced, yet he evidently believes that the risk has been greatly exaggerated by the experience and advice of von Graefe My observation leads to the belief that not only *fatal* results following enucleation during flagrant panophthalmitis are more frequent than our literature would indicate, but that prophylactic enucleation under such circumstances should be avoided for an additional reason, namely that during the activity of panophthalmitic inflammation, enucleation does not possess the prophylactic influence which we recognize as the paramount reason for removal of an eye

In reference to mortality following enucleation, there have been 2 cases within my immediate knowledge, both of whom at the time of operation had panophthalmitis, one case I reported in the *American Journal of Ophthalmology* (Vol III, p 141), the other case occurred but a few weeks ago in a town near by, the particulars of which I have been unable to obtain as yet It seems to me that the occurrence of greater fatality, when enucleation is made during panophthalmitis, and the additional probability suggested by the foregoing, that sympathetic ophthalmia follows enucleation during panophthalmitis much more frequently than it follows enucleation during all other pathological conditions, warrants postponing the operation, at least until

sympathetic irritation makes its appearance, then when the patient has all to gain, he can afford to stake his life against total blindness Sympathetic ophthalmia so rarely follows injuries of the cornea and anterior synechiæ that I am led to believe that the operation of iridodesis has fallen into undeserved neglect

The first and most important consideration in the management of patients in whom conditions liable to lead to sympathetic ophthalmia exist, is the means of preventing its occurrence It is unnecessary to go over the ground so ably traversed by Mauthner in his work upon "Sympathetic Diseases of the Eye" Excepting the small proportion of cases where foreign bodies can be successfully removed from the eye, and those cases where marginal iritic incarcerations can be released, the only preventive measure which, up to the present time, has demonstrated its value, is enucleation, and the question arises, When should preventive enucleation be resorted to? Mauthner, who is generally very clear upon this point, fails to give the lesion or lesions which, in his judgment, warrant preventive enucleation, and I believe interrogation of the lesion is essential to a rational conclusion

It is our duty to seek for the course, which will give the greatest amount of benefit to the largest possible proportion of patients If a certain procedure saved 50 per cent of the patients with a certain lesion from total blindness, but was accompanied with a mortality of 2 per cent ought it not to be adopted? This is a matter which we of course present to our patients for their consideration, but when our patients in turn leave the decision with us, we must accept the responsibility and act upon our best information

We must recognize that sympathetic ophthalmia does not, of necessity, follow any particular kind of injury, that a man may go through life with an eye rendered blind by invasion of a foreign body, or that the ciliary region may be punctured by an osage thorn, and an atrophic globe ensue, without the other eye suffering in the least, but we know that in 100 of such cases, uninterfered with, many would be found blind at the end of 12 years On the other hand punctures of the cornea, incarcerations of the iris in the cornea, traumatisms of the lens, or wounds of the sclera near the equator, while always carrying an element of danger with them, are not followed in any very great proportion of cases with lesion of the other eye Therefore, I believe the first indication for preventive enucleation is the presence of an inaccessible foreign body within the eye, or severe injury of the ciliary region of the globe, and that this indication exists, even if there be retained, to use Mauthner's language, "*a certain amount of vision*," and with me the "*certain amount*" would be *considerable*, if the patient had a piece of gun-cap within his eye, fortunately, however, for us and our patients too, useful vision rarely remains in the injured eye after injuries of this kind My belief in this position is rendered stronger by *Case 9*, related below, in which sympathetic iritis occurred without warning, and within 24 hours of careful examination

While the above applies to the condition immediately following the accident, I should regard the subsequent occurrence of panophthalmitis as a contra-indication to preventive enucleation, for the reasons given above So far as the other class of cases, where serious disease or injury exists, not involving the ciliary region, at least primarily, Mauthner's rule, which he makes, includes all dangerous cases, seems particularly applicable, he says "*My rule in such cases is as follows If the patient is* moderately intelligent, has good surroundings at his home, and can at any moment summon the counsel of a skilful oculist, preventive enucleation is not necessary" Unfortunately this rule in the United States covers only a small proportion of the cases, and is it not best then, in those cases where such surroundings are impossible, to always advise the removal of a hopelessly useless eye?

The diagnosis of sympathetic irritation, using the term technically, referring to a condition threatening the occurrence of sympathetic ophthalmia, and marked by weakened accommodation, lachrymation, photophobia, etc, is rendered difficult by the fact that the symptoms mentioned frequently follow trivial injuries, and may be developed in one eye by straining the accommodation of the other Within the last two weeks I have seen four cases in which the determination whether the condition was the precursor of sympathetic ophthalmia, or was innocent of any dangerous significance, was very difficult In former times, I excluded all cases in which the redness, lachrymation, etc, of the second eye disappeared upon the use of atropine to the injured or diseased eye, latterly, I have made use of cocaine in the same way With this elimination, which makes, perhaps too arbitrary a boundary between safety and conditions belonging to so protean a malady as sympathetic disease, the remaining cases can be looked upon as of the utmost gravity, and enucleation advised without hesitation in the most urgent manner, indeed my rule is, where enucleation is refused under such circumstances, to decline further responsibility in the case In the presence of sympathetic irritation, a moderate amount of vision in the first eye should be no bar to the effort to preserve the second Much has been written concerning the possibility of the injured or diseased eye, preserving greater usefulness of vision than the sympathizing one, my notes furnish 2 cases of doubtful value

Case 6—J. R R, male, æt 47, received a contusion of left eye several years previous, slight posterior synechiæ resulting, about a year later iritis of right eye followed, resulting in extensive adhesions, right eye, S $=\frac{1}{160}$, left eye, S $=\frac{1}{32}$

Case 7—M C, male, æt 35, contusion of right eye at 27, followed by failure of vision in the other eye recently, atrophic disk of left eye Condition of vision, right eye, S $=\frac{1}{64}$, left eye, S $=\frac{1}{200}$

During sympathetic serous iritis and sympathetic plastic iritis, Mauthner advises strongly against enucleation I have, however, enucleated in the early stages of both with good results

Case 8—S W, female, æt 30, at 13 received an

injury, involving cornea and ciliary region of right eye, at the time of observation the right eye was totally blind, the left with serous iritis, S $=\frac{20}{100}$, the right eye was enucleated, and soon after the left became still worse, a week later the nerve was resected and improvement began at once, at the end of four weeks the left eye had regained normal acuteness of vision

Case 9—E W, male, æt 58, while sawing wood slipped, and in falling brought his hand violently in contact with his right eye, when seen a few minutes later no external lesion was found, the anterior chamber was filled with blood, the margin of the iris was detached in the upper and outer quadrant, midway between the cornea and equator there was an apparent subconjunctival laceration, subsequently shown to be rupture of the sclerotic, ecchymosis of all parts in the vicinity of the globe No great amount of inflammatory disturbance ever appeared, the pain was inconsiderable, and with absorption of blood vision improved, and although no view of the interior could be obtained, in seven weeks the vision had increased so that he counted fingers at 6 feet Without any warning, between 10 A M of one day and 9 A M of the following day, sympathetic plastic iritis appeared, he stating that he noticed slight discomfort of the left eye upon arising, and thought he could not see as well, examination showed posterior synechiæ and the presence of flocculent lymph in the aqueous As might be expected, in so recent plastic iritis, the points of attachment yielded to atropine instillations, the pupil dilating irregularly, enucleation was made at once, and the patient sent to bed, the iritis proved very persistent, but eventually yielded, the patient visiting the office 4 weeks after the enucleation, for the first time, S $=\frac{1}{2}\frac{0}{0}$ Three years later I found slight pericorneal injection, iris freely movable, and vision the same

I think, however, that where plastic iritis has existed several days, and especially if atropine fails to loosen the adhesions, there is nothing to gain by enucleation during the active stage, but if, upon subsidence of the inflammation, there remains an apparently good opportunity to secure vision in the sympathetically affected eye, I believe it is best to enucleate before making an iridectomy

I have encountered but 3 cases in which I have made certain, that the sympathetic inflammation had been confined to the iris (or to the iris and cornea), in all of them a fair amount of vision was obtained by iridectomy following enucleation

There is a suggestive scarcity of literature upon the subject of treatment of sympathetic ophthalmia after its full development When the sympathetic inflammation is limited to the iris, serous or plastic iritis, there is still probability of affording relief, but when irido cyclitis or irido-choroiditis occurs sympathetically, there is but little for the surgeon to do I have not referred to the operation of cutting the ciliary nerve or the optic nerve posteriorly, or to evisceration of the globe, with or without the implantation of an artificial vitreous I have had no personal experience with either of them, and from reports of the first, and observation of the last, I have not been favorably impressed with them

In so serious a matter as the effort to preserve one eye after its fellow is functionless, or is likely to become so, considerations of personal appearance are of secondary importance, safety of vision being the object sought for, at every sacrifice but that of life, and I believe that patients have the right, if they so desire, to risk life for the preservation of vision The total loss of vision is but little less serious than the loss of life, and the same rules as to efforts to preserve vision apply, as are foremost in the mind of the surgeon who operates to save life The surgeon selects in amputation the point which will give to his patient the greatest possible opportunity for life, we select in the cases threatened with sympathetic ophthalmia the operation which experience has shown will give the greatest opportunity for vision

---

DENTAL LESIONS CAUSING FACIAL NEURALGIA AND OTHER NEURAL PHENOMENA

Read in the Section on Dental and Oral Surgery, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY ARTHUR B FRELMAN, M D, D D S,
OF CHICAGO, ILL

When invited by the Secretary of this Section of your Association to prepare a paper to read before so intelligent a body of scientific men, representing the two noblest professions to which men have ever devoted time, toil or study, I instinctively shrank from the duty imposed with the conviction that there were many older and more experienced men in the profession who could present subjects of far greater interest than I, but your Secretary persisted and I reluctantly consented to prepare a paper on the above named subject While casting about for a topic on which to write, this subject was suggested to my mind, not because of anything of an original character which I had to present, but by a little episode to which I was compelled to listen while at dinner, and which may not be wholly out of place if related at this time

On the above occasion I was "given a severe pain"—not neuralgic in character, however—by a female fanatic on the subject of metaphysics, who detailed in minutiæ a most extraordinary cure by her metaphysician of a very dangerous attack of facial neuralgia, which had signally baffled the skill of several of the "Eddy Faith School" and other way-up Christian scientists, and this wonderful man had only to convince his patient that the pain was in her mind and it was gone forever As detailed by her, an educated dental practitioner of to day would not require a very active imagination to diagnose this as the old, old story of pulpitis of three or four weeks' duration, the pulp, after a lingering death, had finally expired, to be almost immediately succeeded by suppuration, pericementitis, and the accompanying pain and œdema, of perhaps unusual severity Fortunately for this latest metaphysical ass in attendance,

the pus had formed and the abscess had pointed when he was called to this case, of a class in which he had never been foiled

Who can wonder that two back-to back consultations with such a miraculous man was enough to cause this abscess, or any other, for that matter, to discharge itself freely? The reparative efforts of nature here wrought a tedious cure and an imposter secured glory alone due to her As I listened I thought how much more pain saving and scientific it would have been for a general or dental practitioner to have introduced an appropriate devitalizing application in the early stage of this neuralgic affection and in twenty or thirty minutes' time have saved this poor foolish mortal three or four weeks of excruciating agony

The great number and endless variety of facial neuralgic manifestations have perhaps tortured more people, attracted the attention and baffled the skill of more practitioners of medicine, and luxuriantly supported more quacks, than any other one disease, and they have not, except in isolated cases, wrought more than a temporary relief Why? Because they have not found the cause and then removed it

What is known in medical literature of this pain-demon which constantly or periodically mars the comfort of so many thousands of cowardly, and some hopeless, human beings, and causes the simple endurance of this vast amount of suffering, which saps vitality, wears out the strongest frames and causes disease in those who otherwise might enjoy a life reasonably exempt from ill health? I am compelled to answer, nothing What space is accorded to the subject in the several treatises on the practice of medicine which I have consulted is devoted to the acknowledgement of the ignorance of the subject as regards lesions of the teeth, and a few glimmering generalities on etiology and non-lesion in the affected nerve trunk, etc Indeed, one eminent writer on "Practice" goes so far as to record the following brilliant assertion "Caries of the teeth is an occasional cause of tri-facial neuralgia, but it is by no means frequently referable to this cause " He evidently takes it for granted that "caries" is the only ill which a tooth is heir to

So far as I have been able to discover, and I have examined the literature somewhat carefully, I have found only one writer who has accorded to dental lesions, as a causative agency of facial neuralgia, that place which it deserves, and I think even he was too modest in his assertion of their influence

It is with the desire to add something to the literature of the subject, and also with the hope that, if many medical practitioners do not listen to what I may present, some seed may at least fall on fertile soil—as I am confident it will—and bring forth its fruit, and also a sensibility to the sufferings of our patients and the thousands who are not our patients, but the dupes of quacks and nostrums, that I am persuaded to cope with this subject

With these preliminary sentences I will enter more or less minutely into the discussion of Tic Douloureux, and the principal lesions of the teeth which may provoke it, and at the same time introduce well authenticated examples from daily practice by way of illustration of some of the neural phenomena resulting

To quote a current definition of the term neuralgia, it is a disease the chief symptom of which is very acute pain, exacerbating or remitting, which follows the course of a nervous trunk, extends to its ramifications and seems, therefore, to be seated in the nerve I shall take the ground, notwithstanding the arguments pro and con, that neuralgia is a phenomenon rather than of itself a distinct disease—simply the expression of an acute or remote lesion The derivation of the word itself is from two Greek roots, *νεῦρον* (neuros), meaning nerve, and *ἄλγος* (algos), meaning pain, thus its simplicity of meaning is pain in a nerve Any pain, therefore, may very properly be called neuralgia, and to a great extent is by the masses, unless of such acute character and so localized that it cannot by any possibility be mistaken for a toothache, toeache, headache or backache

It is in this general sense that I shall employ the term in this paper, as it is in this general sense that the term is used by the medical profession as well as by the laity It is a poor philosophy, indeed, to reason that any effect is produced without a cause If neuralgia is a disease, what is its lesion? If it is simply a phenomenon, then what are the most frequent causes of its expression? I believe that in at least nine out of ten of all facial neuralgias the sole and only cause is in, and associated with, the teeth

Doubtless the members of this Association will agree that the conditions known as anæmia, debility, syphilis and miasma are predisposing causes, and I think they will also agree with me that the *prima facie* cause lies nearer the pulp-chamber of the tooth and has a more tangible union with the trifacial nerve than have these general conditions

The lesions of the teeth may be divided into two classes pulp lesions, or those arising from irritation within the teeth themselves, and pericemental lesions, or those manifesting themselves from irritation outside the apical foramen

Mentioning these pathological conditions in the order of their minimum importance, as they occur to me, first, noticing the pulp lesions, we have sensitive dentine as sometimes noticed in superficial and simple caries Irritation from this condition occurs most frequently in patients of low grade temperament with a predominance of the nervous basis and asthenic constitutions The symptoms may range from uneasy sensations, which may be located about the teeth, jaws, cheeks, eyes, nose, etc, to positive neuralgic pain or paralysis, and are usually aggravated by contact with sweets and sours and rendered intense by the simple touch of an instrument

Secondly —Deep-seated caries may or may not cause pulp irritation as above described, in proportion to nearness of proximity of the dissolution of calcific salts to the pulp itself, while the symptoms most to be relied upon are increased pain on contact with extreme thermal irritants, and cessation or remission on application of pain obtunding remedy

Thirdly —Complicated caries, including all cases of almost or complete exposure of the pulp, dying pulps from too near proximity of metal fillings or other predisposing causes This is perhaps the most fertile of all the lesions, and at the same time most easily diagnosed and treated

The symptoms may be paroxysmal and remittent, intermittent or constant pain, not always positively located, very severe during paroxysms, throbbing or jumping and usually increased at night

Fourthly —Calcific formations within the pulp-chambers, which are all pathological conditions, sometimes giving rise to types of neuralgia difficult in diagnosis and obstinate in treatment

These conditions are usually found in patients of sthenic constitution, and as classified and defined by Prof G V Black in the "American System of Dentistry," are six in number and as follows

1 Secondary Dentine —A new growth of dentine more or less regular in formation, excited by abrasion, decay or other injury by which the nerve fibrils are subjected to irritation at their distal ends

2 Dentinal Tumor within the Pulp Chambers — An erratic growth of dentine into the pulp chamber united to the wall by a pedicle, the structure usually being very irregular

3 Nodular Calcifications among the Tissues of the Pulp —These are smooth or nodulated stony masses of dentinal tissue deposited among the pulp tissues as a result, probably, of irritation

4 Interstitial Calcification of the Tissues of the Pulp,—which is the counterpart of calcifications elsewhere in the body

5 Cylindrical Calcifications of the Pulp —This form occurs infrequently, and always in the root canals, the tissues of which are probably in a state of fibrous degeneration

6 Osteo Dentine —An erratic formation showing both lacunæ of bone and dentinal tubes

The lesions of this classification are somewhat similar in the manifestation of symptoms, by no means always producing neuralgic trouble, though pain from secondary dentine impinging on the peripheral termination of the nerve fibrillæ of the pulp, causing its pressure and recession, and chronic irritation from pulp nodules and erratic growths, is not of unfrequent occurrence

Fifthly —Abrasion of the teeth, either mechanical or chemical, is not an occult but frequent cause of distressing and prolonged neuralgic pain The wearing down of the crowns of the teeth from attrition or otherwise, causing irritation, congestion, pressure on nerves and consequent reflex pain

As has been said, any and all of the above pathological conditions, as well as many others connected with the teeth, may cause hyperæmia of the pulp, predisposition to its death and all possible variety in neuralgic phenomena

Among the most frequent and painful of the second class, or pericemental lesions, we have

1 Pericementitis —This is usually an acute inflammation caused by irritation of the pericemental membranes by mephitic gases escaping from the pulp chamber through the apical foramen, resulting from putrescent pulp

The symptoms are usually decided soreness, acute throbbing pain beating with the circulation, violent suffering upon concussion of tooth, obliterated health line, dull heavy pain diffused over the entire side of face, neck and head, also a peculiar bluish appearance of tooth on comparison with adjacent ones, and lack of pain on thermal change

In many instances the escape of mephitic gas is slow, the irritation of pericementum correspondingly chronic, in which condition pain of a reflex character is frequent and severe, and has been observed to extend over a period of many years

2 Exostosis dentium —A bony enlargement of the roots of teeth caused by slight and continued peridental irritation, exciting deposition of salts at the point of irritation

The varieties may be nodular, circumscribed or apical or diffused, and while the condition is not always accompanied by pain, very many complicated cases arise in practice

3 Absorption of Permanent Roots —A pathological condition analogous to absorption of other hard structures which, leaving the end of the root rough, spiculated and uneven, almost universally causes irritation resulting in severe reflex manifestations

4 Retention of diseased roots

5 Pyorrhœa Alveolaris and accretions of salivary calculous impinging on the gingival border

6 Mal eruption of and Impaction of the Wisdom Teeth

7 Diseased Antrum arising out of the foregoing or other causes

I am confident every dental practitioner before me can cite from his own practice case after case of facial neuralgia of severe type as an effect produced, illustrating each of the above distinct lesions as the cause

In connection with the close of this paper I wish to call your attention to some of the other very interesting neural phenomena which may be caused by dental lesions, through inosculation of the nerve-branches and reflex action, and perhaps I cannot do this in a more interesting way than to briefly relate the histories of a few cases from practice as related by those who have observed them

First A case, copied from the June number (Items of Interest) of the *Dental Independent*, and taken by that journal from the *London Dental Review* The patient had suffered fourteen years with dreadful pain in the eye, accompanied by a continual flow of tears and intolerance of light A diseased tooth was extracted from the upper jaw on the same side on which the painful eye was situated, when the the eye was speedily restored to health

Second An unusually interesting case of paralysis of an arm from reflex odontalgia through inosculation of the trifacial nerve and brachial plexus, as related to the students of the Philadelphia Dental College by Prof J Foster Flagg A Western Judge (from Arizona, I think), had suffered with paralysis of an arm for some months before going to Philadelphia for medical treatment, which he had received there for a space of three months, without success, when he incidentally called on Dr Flagg for dental

services Had experienced no pain in teeth, but on examination complicated caries was found on distal surface of a lower left bicuspid On probing same there was decided arm response, *i e*, pain, numbness, etc, in fingers and hand The pulp was sedated and devitalized, and immediately arm recuperated, and in something like a week the paralysis was completely cured

Third Another case related by Prof Flagg, of intermittent paralysis of the muscles of deglutition caused by general dental irritation from sensitive dentine and vitiated oral fluids Patient was a young lady some 28 or 30 years of age, who was at times afflicted with paralysis of deglutory muscles, intense paroxysms of pain, usually excited when sensitive dentine was irritated by pressure of foods or the tongue, and also brought on in all their intensity by the touch of an instrument, when the agony of expression of the countenance and drooling of saliva were pitiful The introduction of ½ dozen amalgam fillings wrought a complete cure

Fourth A case of severe ocular pain occurring in the practice of my preceptor, Dr Daniel B Freeman, of this city, some years since The patient had suffered from a painful eye and been under the treatment of an oculist for six months without improvement While waiting for the arrival of the physician one day he complained of terrific supraorbital pain, and entreated that something be done for his relief, and in compliance tr of aconite was applied over supraorbital foramen, when instantly the pain flew as if by magic to a partially covered root of a tooth on the same side of face The root was extracted, found to be exostosed, and the pain in the eye never returned

Finally A case of diffused facial neuralgia from abrasion, secondary dentine and exostosis Patient 50 years of age, sthenic constitution, had suffered from neuralgia for a year and a half or two years, four roots were present and the balance of the teeth in the upper jaw much abraded from attrition The roots were extracted and found exostosed Pain still continued and finally, at two or three sittings, the abraded teeth were all extracted, and no further trouble has been experienced

I would not have you understand me to say that all suffering is caused by tooth lesions, neither do I assert that all pains and aches traceable to the teeth for their cause, rightfully or technically come under the head of neuralgia I do claim that very many more of them than is suspected are occasioned by these lesions To the end of time we will all doubtless be frequently brought face to face, in our efforts to diagnose obscure cases, with a black, impenetrable wall, so high and broad that we cannot see over or around, so thick that no ray of light will shine through This must necessarily be the case, but to find the cause and remove it should be our highest and chief aim, failing in this, we can do no less than our predecessors have done—treat facial neuralgia on the sedative plan

PUERPERAL TETANUS

Read before the Medical Society of the District of Columbia, May 18, 1887

BY C V BOARMAN, M D,
OF WASHINGTON, D C

I was summoned in haste to see Mrs T, in her second confinement, March 16, 1886, at 8 30 A M The messenger stated that there appeared to be serious trouble, as she had been in labor since the preceding evening, a midwife being in charge I at once went to the assistance of the woman, and found her suffering acutely and anxious for aid Upon making an examination, my hand encountered the child's hand and arm (the former lying in the vulva), the os uteri was so firmly contracted around the child's shoulder that it was impossible for me to force my hand beyond it, nor could I dilate it, although I worked assiduously for over an hour The womb was in a constant state of action, brought about by numerous doses of fl extract of ergot, administered by the midwife in charge the preceding night, an ignorant old woman Seeing that it would be impossible for me to accomplish podalic version alone, I asked for and obtained consultation Dr A McWilliams having been called, he made several ineffectual attempts to introduce his hand into the uterus

Concluding that it would be impossible to either turn the child or convert it into a head presentation, we then called the husband and laid before him and the wife the two operations, Cæsarean section and embryotomy, they would not allow the former, but willingly gave their consent to the latter, the child having been dead some time

Having administered ether to the patient and produced full anæsthesia, I again attempted to introduce my hand into the uterus, but could not overcome the rigid contraction of the os uteri, which hugged the child's shoulder so tightly that I could not even insinuate the end of my finger between it and the child Dr McWilliams also made an attempt to do so but failed

Seeing the absolute impossibility of delivering the child, we at once, with the assistance of Dr Briscoe, proceded to perform embryotomy After working for over two hours we succeeded in removing the child, which was far advanced in decomposition After delivering the placenta the womb contracted nicely, the woman reacted from the anæsthetic, and appeared to be quite comfortable

March 17 —Mrs T was very cheerful and doing well, asked for food, and said she had passed a good night Lochia normal and satisfactory I again saw her late in the evening, and found her restless and complaining, slight febrile reaction, quick pulse, and some abdominal tenderness

The mother of the patient requested me to see a man in the next room, stating that he had been sick for some time with erysipelas, and that he had a large abscess developing beneath his right ear I declined after giving my reasons for so doing, and ordered his immediate removal to a hospital if possible That being out of the question he was carried to a distant part of the house and the room well aired and fumigated,

it was separated from the lying in chamber by a board partition only, a very dangerous neighbor for a woman in confinement

March 18 —We met quite early and found our patient suffering with a well marked case of puerperal fever, which ran its course in a few days, and convalescence had begun to establish itself, when, upon making my evening call March 23, I found Mrs T complaining of a stiffness of the jaws and an inability to open her mouth sufficiently to take nourishment She had great pain in the back of her neck, and there was also considerable muscular rigidity, the peculiar *risus sardonicus* was present I at once concluded that we had a case of tetanus to contend with, but the woman being of a highly neurotic type, subject to hysterical manifestations, and having always been treated as a spoiled child, I hoped that it would turn out to be transitory

March 24 —As indicated by the symptoms of the preceding evening, Mrs T 's was a well marked case of tetanus, the jaws locked, intense pain the back of the neck, and a rigid contraction of the longitudinal muscles, they were in a state of tonic rigidity, opisthotonos was constant and well marked, the mind perfectly clear, pulse frequent and small, temperature increased (but having misplaced my chart I can not give its exact height), speech and deglutition difficult and painful The abdominal muscles were alternately rigid and relaxed and respiration painful The spasms recurred with great frequency till death put an end to her sufferings on the morning of March 25 No post-mortem examination was allowed

The case just reported was certainly a most formidable one The womb through necessity was subjected to considerable handling, and to the introduction of instruments into it, as the delivery was a most tedious process and the child removed in pieces, as its limbs were so softened by decomposition that they would stand but little traction without separating, besides, the mother had been freely dosed with ergot by the incompetent midwife the preceding night, causing the uterus to be in a state of rigid contraction

Gallabin[1] states that puerperal tetanus is very rare and that no instance of it occurred in 46,089 deliveries in Guy's Hospital Lying in Charity, and that he had only met with one case

My patient had every attention, no exposure to cold, absolute cleanliness, was well washed and syringed *per vaginam*, with warm, carbolized water, and also bi chloride of mercury solution, and even the interior of the womb received attention

Puerperal tetanus resembles surgical tetanus in that it arises from some irritation connected with the local traumatic condition in the uterus or vagina No doubt this had considerable to do with the production of tetanus in my case Dr Robert Reid[2] states that injuries of the internal organs do not appear to have much tendency to produce tetanus, which appears to be the case, as the uterus is subjected to more rough handling, scraping with curetts, lacerated and torn during labor, by its process and instruments in the hands of physicians and others Yet the patients make good recoveries, and it is a rare occurrence for tetanus to follow the above injuries, although it is occasionally caused by a small piece of placenta, left in the womb, as was the case in a patient of Dr Banga's, but his followed an abortion

Upon looking into the literature of tetanus following gestation at full term, I find many causes described Garrigues,[3] who has looked into the subject with great care, succeeded in collecting 32 cases, which he has tabulated, giving their supposed cause, mortality and treatment According to his table there were only 3 recoveries Those following abortion were 25, with 2 recoveries In the majority of the cases there existed complications at the time of the confinement, such as forceps delivery, retained *placenta, ruptured perineI* and hour glass contractions, necessitating dilatation for the purpose of placental delivery and hæmmorrhage

Under the heading "Puerperal State and its Complications," in the catalogue of the Army Medical Library, puerperal tetanus is of rare occurrence After a careful search I succeeded in finding a few very interesting cases which I will take the liberty of reciting in part as they are of great interest, giving their supposed cause where possible

Case 1 —Reported by Quinton Gidbon,[4] was that of a woman æt 32 years, primapara, labor tedious, pains so distressing that he administered chloroform for their relief from time to time At noon the head being well down in the lower strait, and the pains having abated, he delivered with forceps, the placenta being retained by an hour-glass contraction, he was compelled to introduce his hand and deliver it The patient complained constantly during her labor of inward heat and thirst, which continued after delivery, in 48 hours these symptoms abated, and she recovered so rapidly during the following 3 days as to be considered convalescent On the morning of the 12th she complained of slight stiffness and pain in the muscles of the neck and lower jaw, with difficulty in swallowing, all the symptoms pathognomic of tetanus followed, and she died in 60 hours after their first appearance Gidbon stated that the above case was his first one in a practice of 40 years Was this traumatic tetanus brought about by injury done the parts by forceps or hand?

Case 2 —Reported by Dr R C Bennington,[5] was that of a woman æt 30, secundipara, was delivered with forceps after great trouble, perineum was torn, child still born She died in 24 hours after the first symptoms became apparent, of tetanus, which took place on the seventh day after confinement Here we also have a traumatism

Case 3 —Reported by Dr McDonald[6] A secundipara, her delivery was natural and easy, and of only a few hours' duration March 9 first symptoms of tetanus became apparent, spasms of an opisthot-

onic character set in, and all other manifest signs indicative of the above disease The patient died the same day In this case no traumatic cause existed, the onset of the disease was sudden and its termination very rapid The post mortem examination presented some lesions of the brain, which looked as if eclampsia was associated with it

Case 4 —Another peculiar case without traumatism is that of Dr John Haddon[7] The mother of 8 children was confined March 11 Labor slow but normal Patient did well until the 13th, when a rigor occurred with abdominal tenderness She appeared better in the evening

March 14, symptoms of tetanus, otherwise doing well, lochia normal, no abdominal tenderness, but the uterus was large and rather soft as felt through the abdominal walls

March 17 Tetanic spasms of the jaws and trunk, speechless, but seemed conscious Upon making a vaginal examination, on the right side of the womb, which was still large and flabby, easily admitting the hand, was discovered some foreign body or substance, it felt in consistency similar to the uterus and seemed incorporated in its walls Several attempts were made to remove it, but had to desist for fear of injury to the uterine substance

The patient died of tetanus at 1 30 A M, March 18 No post mortem examination was made

Case 5 was one of forceps delivery reported by Dr Kuhn,[8] followed by tetanus on the eleventh day after delivery, and death on the thirty-eighth day

Case 6 —Ehrendorfer[9] reports an interesting case of labor followed by tetanus which recovered Attempts were made to deliver with forceps, but unsuccessfully Craniotomy was resorted to and a full term child delivered On the fourth day after the operation symptoms of tetanus appeared, on the seventeenth day she left the bed, and on the twentieth day she was discharged

Case 7 —Werner[10] reports a case to which he was called to check hæmorrhage after delivery, a midwife having had prior charge Tetanus set in on the ninth day, and patient died 6 days later

Case 8 —Dr Keeting[11] reports a case attended by considerable hæmorrhage, but the patient reacted nicely and was doing well, when tetanus set in on the eleventh day and she died soon after

Case 9 —At the Lying-in Hospital, Prague, in the service of Dr Rubeska, a case of tetanus following a forceps delivery occurred The patient died Upon making a post-mortem examination there was found metritis and endometritis Reported by Dr W R Endres[12]

Case 10 —Reported by Dr Ditzel,[13] who was called on account of hæmorrhage after delivery of a living child, found her very anæmic from loss of blood, uterus very high up, flabby and enlarged April 6, 3 days after, symptoms of parametritis, which apparently grew better till April 12, when tetanus set in and she died, 2½ days after first signs of tetanus, 10 days after delivery

Puerperal tetanus, although known to the ancients and mentioned by both Aretæus and Archigenes, apparently escaped the notice of our leading obstetrical writers, until Sir James Y Simpson's attention was drawn to it in 1854 He was the first to write an elaborate article on the subject, giving the record of 28 cases collected by him from various sources He was followed by an exhaustive treatise on the same subject by Garrigues,[14] to whom I am indebted for much of my information In 1849 Pitra Aubinais[15] reported 3 cases

In America and Europe puerperal tetanus is very rare, even in our Southern States, where we have many negroes and a high temperature, the latter being mentioned as a cause

In India, Waring[16] states that in 3 years 232 women perished from puerperal tetanus at Bombay Colored races are more prone to it than white, and hot climates are predisposing elements, particularly during the wet seasons It is more common in the country than in the city, and very rare in lying in institutions Advanced age is frequently a cause, particularly after abortions, as are also first pregnancies, according to Garrigues' table To show how very rare this disease is Merriam collected 10,190 cases of difficult labor with 106 deaths, and only 1 died of tetanus

The puerperal state itself is a predisposing cause, particularly in neurotic females, as are also mental excitement, grief, and anxiety Hæmorrhage, by its debilitating and prostrating influence, is a prominent cause of tetanus

Suppression of the lochia, or a profuse perspiration, are looked upon by Pitra Aubinais as unfavorable symptoms and likely to be followed by tetanus

Throat troubles occasionally precede it, Garrigues mentions 3 cases where this was the case

Injuries to the womb, vagina and perineum, made either by instruments, or the hand of the operator in turning and the delivery of retained placenta, particularly where hour-glass contractions exist, are exciting causes of tetanus

The retention of small pieces of the after birth or its membranes is dangerous, and where no other cause can be found should be carefully looked for

Carl Schroeder attributes septicæmic influences as causes of lock-jaw in either abortion or gestation at full term Exposure to cold after confinement has been followed by tetanus

One great reason why we do not meet with this disease oftener is because the uterus is itself or almost entirely supplied by nerves from the sympathetic system, and, as stated by Curling, tetanus is more easily excited by lesions of parts supplied with nerves from the cerebro-spinal system than by those supplied by the sympathetic system

THE USE OF THE DEEP BURIED CONTINUOUS ANIMAL SUTURE IN LAPAROTOMY AND PERINEORRHAPHY

Read by title in the Section on Obstetrics and Diseases of Women, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY E W CUSHING, M D,
OF BOSTON MASS

In his operation for restoration of the perineum, the lamented Schroeder lately used two or even three layers of continuous catgut suture, superimposed one on the other and running from before backward, and then in the reverse direction, thus building up a perineum before he united the vaginal mucous membrane

Jenks' operation for ruptured perineum proceeds, as you remember, by splitting the septum between the rectum and the vagina, dissecting it in both ways until the adhesions are freed, and then, by bringing the lateral surfaces together, the incision, previously horizontal, is made vertical Jenks removes the flap of vaginal tissue thus freed Dr Marcy has modified the operation by retaining this flap, uniting its edges in a straight line, continuous with the new perineal raphe To hold the parts better in apposition he inserts pins in each side, which are united in the vagina and outside of the body by projections with hooks or eyelets on them

Now, in moderate cases of rupture of the perineum, the buried continuous suture of Schroeder may be adapted to the operation, and I have used it in this manner Commencing at the very bottom of the wound made by splitting the septum, as already described, one end of a piece of tendon or catgut is attached in the median line, and then the sides are brought together by stitches taken with a large curved needle, each stitch taking up more tissue on alternate sides, until three or four on each side have been inserted, then the stitches are taken deeper so as to reach the ends of the sundered transverse muscles of the perineum, and draw these together These stitches may be taken deeply with safety, because there are no vessels to be injured except the pudic arteries which lie close under the rami of the pubic bone The rectum is of course carefully guarded from injury by one or preferably two fingers in it, and the whole operation can be conveniently performed under irrigation with a sublimate solution 1 2000

Each stitch thus reinforcing the previous one, the continuous suture brings all the tissues into close apposition, leaving no pockets, and I am now content to dispense with the use of pins, as by the above method there is no dragging of the tissues out of their normal position by any bag-string action of threads or wire

The end of the long continuous suture should be cut off, after securing it, and afterwards buried by bringing together, in the median line, the edges of the vaginal mucous membrane in the usual manner By thus burying the end of the suture there is less chance of septic matter creeping into the wound at the point of emergence of the catgut

I am using this method, with excellent results, even in cases where the rupture extends into the rectum Here the lower edge of the split septum is doubled on itself, and becomes the two edges of the rent in the rectum, to be united from the anterior or raw surface with the finest silk continuous suture

I turn down the point of the flap of vaginal mucous membrane so that the anterior end of the union of the parts is Y shaped

In regard to the use of the buried continuous animal suture in laparotomy, it was reported to me some months ago that Prof Thomas was closing his abdominal incisions in this way, and I have since then used it with great satisfaction Of course it is easy to see that, if the abdominal incision is made under irrigation down to the peritoneum, although strong antiseptics cannot be used in the abdominal cavity, yet it is very desirable to retreat from the peritoneum, if I may use the expression, with irrigation of the abdominal wound, in order to avoid mural abscess, etc

Now this is done as follows the peritoneum is first carefully sewn up with a continuous suture of fine tendon or catgut, and then the sublimate irrigation can be turned freely into the wound When this is well douched and clean the sheath of the recti muscles is to be carefully united with the same suture, and then the tissues held in apposition in order to prevent accident during vomiting, etc

Dr Thomas does this in the following manner, as I observed lately when he kindly explained his method to me during an operation at the Woman's Hospital

Preluding that after sewing up the peritoneum he is careful, in uniting the muscles, to include the edges of the line of union of the peritoneal incision, in order to avoid pockets, he passes two or three silver wires through the skin and fat down to and slightly into the muscular layer These silver sutures are tightened and twisted after the skin has been united by the continuous suture

I have drawn the fat and cellular tissue together without the use of the silver wire, using a curved needle in a manner analogous to that described in speaking of the perineum operation That is, the curved needle carrying the same suture is entered horizontally first on one side and then on the other, in the wound, not through the skin, thus bringing the fat and connective tissue together, so that the incision in the skin comes almost together, and the wound is effectually guarded against gaping or accidental rupture The end of this long suture should now be fastened, cut off, and buried The skin brought together neatly, with another animal suture, and a dressing employed which I think is of great value That is, the irrigation fluid is carefully dried from the skin with sublimated cotton and the wound painted with a saturated solution of iodoform in flexible collodion, a little absorbent cotton is laid over this and saturated with the iodoform collodion, so that the wound is hermetically sealed This dressing, if all goes well, need not be removed or changed There are no stitches to remove At the end of some three weeks the piece of iodoform cotton is removed, carrying

with it the bits of catgut which were external to the skin, the rest is all absorbed or organized

There are one or two points of caution to be observed in the above procedure the first and most obvious is to avoid wounding the bowel when sewing up the peritoneum, and the best way to avoid this is to lift up the ends of the incision, one by the suture and the other with a blunt hook

Secondly, not to draw the continuous suture too tight, for it brings the surfaces in apposition everywhere and not at certain points only, and if drawn tight may strangulate the tissues

Thirdly, particular care is necessary with so long a thread that it may not become soiled or infected during the different parts of the operation Neglect of either of these points may be fatal

COCAINE, AND ITS EFFECTS

BY GEORGE N MONETTE, M D,
OF NEW ORLEANS, LA

Cocaine has been the vaunted remedial local anæsthetic in all forms of pain and suffering, yet it seems that its use in dentistry cannot be availed indiscriminately I have been called a number of times, by a neighboring dentist to attend his patrons, to whom he had given cocaine hypodermically, and without anæsthetic influence, *per contra*, a decidedly deleterious effect had been wrought in each person, requiring several hours for its complete counteraction by the use of opiates and stimulants

The first case to which I was called was that of a young man, single, and a saddler by occupation, by the incidental right of his trade, a strong man, yet under the deleterious influence of cocaine, was completely unnerved The dentist had inserted the cocaine in the gums When seen, the patient was bathed in a cold perspiration, his eyes glistening, yet the pupil was not dilated complaining that he was blind, and that he would die, asking to be held Pulse was much accelerated, feeble, soft and compressible In other words, he really acted as if deranged I gave morphia subcutaneously, and with good effect

Case 2 —I found a colored woman on the floor in the dentist's office complaining of being dizzy, unable to walk, of being sick, with vertigo, pulse slightly increased in frequency, not cold Somewhat excited, no perspiration She recovered within two hours and without any remedy save the inhalation of ammonia

Case 3 was a young man similar to *Case 1*, yet not quite so strong, but with identical complications, which alarmed him very much I gave him morph sulph hypodermically, with the inhalation of aq ammonia and nitrite of amyl, with prompt benefit In each case the features were severe, yet not dangerous

MEDICAL PROGRESS.

PAPOID AND PEPSIN —PROFESSOR D FINKLER draws the following conclusions from some comparative experiments between papoid and pepsin From three experiments with meat it was seen that papoid shows a more energetic peptonizing power than pepsin, and specially so when the proportion of the liquid to the albumen is small—*i e*, in the proportion of concentration in which food generally exists in the stomach and in the intestines The great variability in the quality of commercial pepsin (some of which will under the most favorable circumstances not peptonize more than 20 per cent, of the albumen of the meat) gives papoid also the preference, as it is made of one uniform quality

Experiments with hard-boiled eggs showed that they are better digested by pepsin, if the quantity of liquid is larger in proportion As soon, however, as a more concentrated mixture is employed superiority of the papoid is at once evident

What effect can be obtained by the ferment in the human body?

a Concentration of the solution is of first importance It is impossible to create in the stomach and intestines such amount of liquid as would be favorable to the effect of pepsin The conditions, therefore, are very much in favor of papoid

b Importance of the Reaction —Pepsin acts in the stomach, but not in the intestines as in the latter The reaction is neutral or alkaline Papoid has little effect in the stomach, as the reaction there is acid When, however, the stomach is neutral or alkaline, papoid will peptonize, while pepsin will be useless The degree (amount) of acid reaction in the stomach differs greatly, especially in a stomach out of order, in which case the acid can be so highly acid or alkaline that pepsin would be of no value at all In the treatment of stomach catarrhs we will, moreover, find that, as a general rule, the contents of the viscus have been rendered artificially neutral or alkaline by the administration of remedies, so that in these cases pepsin will have absolutely no effect Papoid, on the contrary, will act energetically

c Regarding the Time Available for the Digestive Ferments to Act in the Body —In the case of pepsin this is necessarily very short, as the action ceases when the food enters the alkaline reaction of the intestines In the case of papoid, which can act well in alkaline reaction, the time is practically unlimited, as it continues acting on the food during the whole time it continues in the body For all these reasons the conditions for the effect in the human body are far more in favor of papoid than pepsin, and especially as under existing circumstances (high degree of concentration) papoid has been shown to act much more energetically It is only too clear that the preference should be given to papoid as a digestive ferment for the treatment of dyspepsia Besides dyspepsia, the papoid is of great importance in the treatment of diphtheria

Its effective power consists in the circumstances that no free acid need be present in the application,

and further that the moisture of the diphtheritic membranes is quite sufficient to allow the ferment to dissolve the solidified substances of the membranes No other ferment has so far been able to obtain these results It is on this account that many competent experimentalists and specialists have lately made observations

From all these circumstances there is no doubt that in papoid we have a ferment which has a great future before it, and it is for this reason that I have made a special study of the manner of preparing the papoid, and I have had the satisfaction of obtaining the most favorable results from its use in the treatment of disease —*Therap Gazette*, Aug 15, 1887

TUMORS OF THE BREAST TREATED BY ELECTROLYSIS —DR ALFRED C GARRETT, of Boston, read a paper on this subject at the recent meeting of the IXth International Medical Congress Many, or most of the tumors that so frequently occur in the human breast, we find can be completely cured if treated while young, or new—that is, while in the first stage of existence—by certain mild applications of electricity

In the first place, to obtain uniform success by this method, we must plan to find these tumors as soon as possible after they form in the breast, while they are in a curable stage in the majority of cases However, we already know we cannot assume that every morbid lump that grows or appears in the human breast begins from the first a simple or non-malignant tumor, though the most of them seem to do so, judging from the uniformly successful results of these treatments by electricity when applied to the selected, new, or recent tumor

It is determined that here we must choose the form of electricity and method of application as carefully as we seek to find the curable cases, for we are not to resort to the usual electro puncture needles, knife, wire, nor any active destructive electrolysis, nor any other means that produce solution of continuity We are to employ simple surface applications of certain graduated, galvanic, steady currents, through peculiar, large, soft, and moist electrodes, so adjusted close to each side of the tumor as to cause this gently chemical current to completely permeate, and wash through the whole mass from side to side in its deeper parts, mainly in direction toward the axilla, for about half an hour at each *seance* It is not enough to simply apply the two electrodes to the surface of the breast or in any manner Moreover, we need to use a milliampèremeter to measure the current that actually passes through the tumor and gland, also a key board that can enable the operator to pick up and increase the current, cell by cell, to the tolerant and efficient strength, which will be from ten to fifty milliampères The current required for each individual case cannot be stated in exact terms, as it is found in practice there is a wide difference in the resistance, tolerance, and effect in different persons, yet this point is of great importance

The result is, that out of 186 tumors treated since 1864, a record of them having been kept and looked after, 157 disappeared and have remained well Several others did not quite obliterate, however, but left a small nodule the size of a chestnut, which in every case disappeared or remained benign *Medical Record*, Sept 10, 1886

PREVENTION OF PUERPERAL SEPTICÆMIA —DR ARCHIBALD D MCDONALD says "Heterogenetic," or more plainly, inoculated septicæmia, should be unknown That is the ideal, and I believe it may be realized by the following method, which is an intensified form of that used by a brother practitioner who had some unfortunate experience which led him to appreciate the benefit of using iodine in obstetric practice Dr Wynn Williams strongly advocated iodine fumigations I believe Well, (1) the nail brush is to be used before leaving for the case, (2) using warm water and soap not previously used, the hands are washed in the patient's room, or room adjoining as the case may be, then (3) about a drachm of liquor iodi is added to about a pint and a half of warm water, and the hands thoroughly rinsed in the mixture, (4) carbolic oil (1 to 20), or in cases of forceps or turning, preferably fresh benzoated lard is used for lubrication, and the examination of the patient proceeded with

During the progress of the case until delivery takes place the iodized water is occasionally used, and instruments are thoroughly washed (blades and handles) with it Of course, in ordinary practice one avoids unnecessary handling of erysipelas, scarlatinal, ulcerating sores (such as scirrhus), and other infectious cases, as well as of dead bodies, or making of *post-mortem* examinations, or even shaking hands with anyone who has been in attendance on any septic case whatever

"Autogenetic" septicæmia, I need scarcely say, is rendered less likely by avoiding lesions and remnants of secundines, through not rupturing the membranes too early, giving timely instrumental help when required, and in doing so carrying the forceps handles well forward, somewhat approaching a line parallel to that joining the umbilicus and coccyx, when the body is in the straight position, so as to lessen the danger of perineal laceration, and by careful expression of the placenta, and gentle extraction of the membranes The same precautions in managing labor of course also help to diminish the chance of septicæmia by inoculation Should the hands become a little hardened by the iodine, rubbing with vaseline and the use of kid gloves during sleep will remedy that not very important matter I do not require to occupy space with evidence in support My cases have included putrid fœtus and emptying uterus of secundines, removing placenta in abortion with vulsella and uterine forceps, adherent placenta, turning, and the various malpresentations, as well as the ordinary cases, extending over a period of six years There has been only one case of septic pneumonia, and there I was stupid enough to use oil which I was given in the house, for lubricating the forceps It was one of my early cases From complications following labor, too, I have been wonderfully free I com-

mend the practice to be used more widely than it now is —*British Medical Journal*, Sept 3, 1887

DIGESTION OF CARBO-HYDRATES —The paper of Ellenberger and Hofmeister, recently published in *Biedermann's Centralblatt*, contains a summary of their long continued researches on this subject They have experimented upon the horse, and their conclusions are by no means identical with those that have hitherto been received An abstract, by Mr J Fletcher, of this important paper appears in the current number of the Journal of the Chemical Society, and it is so lucid and concise that we reproduce it almost *in extenso*

"The action of saliva in the process of mastication is shown to be more mechanical than chemical The quantity of saliva used depends on the dryness and roughness of the food rather than its contents in starch, and the authors think that the chemical activity of saliva owes much to spores, which, floating in the atmosphere, mix with the food and assist in the fermentation process A digestive action of the mixed food takes place in the stomach when the acidity due to hydrochloric or lactic acid does not exceed 0 03 to 0 04 per cent The left section of the stomach of the horse does not secrete a gastric juice, this is the function of the right portion The gastric juice of the horse contains lactic, fatty, and amylaceous ferments—the latter in small quantities Cellulose is not digested in the stomach of the horse, but muscle, fat, gelatine, and flesh generally are easily digested, bone and elastic tissues more slowly Pepsin operates actively only when acids are present, about 2 per cent of lactic acid or 0 2 per cent of hydrochloric acid being necessary The activity of pepsin does not increase in proportion to its quantity after reaching a certain point, but it rather becomes injurious The acid which appears first in the digestive process is lactic acid, and later hydrochloric, at the time of greatest activity lactic acid is present in the upper and lower extremities of the digestive tract, hydrochloric acid being found in the intervening part The digestion of starch in the stomach of the horse lasts for about two hours, that of albuminous matter takes place later, and occupies three or four hours after the eating of the food The drinking of water immediately after food does not appear to hinder digestion The secretions of the intestinal canal unite in themselves all the properties of the gastric juice, and can act as a substitute for it, and are particularly energetic in the decomposition of fats The duration of the digestive process in the horse is long, lasting almost three days A very active lactic fermentation of sugar takes place in the stomach and intestines, but the authors do not say that all the sugar which is lost in the course of passage is lost in that way, it is more probably reabsorbed"—*Lancet*, August 27, 1887.

CINQUEFOIL IN NIGHT-SWEATS —DR SAMPSON POPE, of Newberry, S C, writes to the *Therapeutic Gazette*, of August, 1887 I desire to call the attention of the profession to a vegetable remedy, native to our soil, for that troublesome accompaniment of wasting diseases, night-sweats Atropine is a good remedy, and in the majority of cases answers the purpose, but atropine is a very strong medicine, and must be used with great care A simpler medicine, answering the same purpose, would certainly be better King recommends it, but I did not get it from him, *I got it from an old negro*—from the same source that the profession got gossypium The remedy is one indigenous to the whole country, it is therefore within the reach of us all, it is the cinquefoil, *Potentilla canadensis*, called by some botanists *Potentilla sarmentosa* I have stopped night-sweats with it when *atropine failed to relieve* It is pleasant to take, when drawn it has an agreeable odor, much like table tea The manner of preparation is to pour boiling water on a handful of the vine, leaves, and root Let the patient drink *ad libitum*

A supply can be obtained through the Southern purchasing agency of Messrs Parke, Davis & Co, Charlotte, N C, or through Messrs Wallace Bros, Statesville, N C, or, if not too busy, about your own homes I hope that some manufacturing chemist will (should I be found to be correct in my estimate of it) give to the profession a fluid extract of the root and plant

CUTANEOUS SENSIBILITY IN RHEUMATISM —L BARBILLION says that as a rule disturbances of cutaneous sensibility are present in this affection Ordinarily the tactile and pain sense is diminished, sometimes increased The sense of heat is also affected, but most frequently electrical sensibility is disturbed, and it alone may be affected For a more or less long time after the attack there is more or less complete anæsthesia and loss of sensibility to Faradic excitation These changes are generally limited to the part of the skin covering the affected joint, but may extend over the entire limb The diminution of the reflexes, the muscular paresis, the muscular atrophy following indicate, as do the disturbances of sensation, that the nervous system is affected—acute articular rheumatism —*L'Union Medicale*, September 13, 1887

AMYL-HYDRATE AS AN ANÆSTHETIC —At the last meeting of the South-west German Association of Neurologists and Physicians for the Insane, PROFESSOR VON MERING announced that he had found a most valuable anæsthetic in amyl-hydrate (tertian amyl-alcohol), that he has tried the same in sixty cases of insanity, paralytics, and melancholia, in somnia caused by nervousness, and in feverish diseases, a dose from 30 to 75 minims, sleep lasting from six to eight hours, no bad results, the taste is pleasant as that of paraldehyde Von Mering gives this formula

℞	Amyl hydrate	ʒi
	Aquæ dest	ʒx
	Ext liquirit	ʒi

—*Therapeutic Gazette*, Aug 15, 1887

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE $5 00
SINGLE COPIES 10 CENTS

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters

THE TREATMENT OF RECENT CASES OF INSANITY IN ASYLUMS AND IN PRIVATE HOUSES

The above constituted the subject of DR G FIELDING BLANDFORD'S address before the Ninth International Medical Congress in Washington, D C , and it was presented with the ability and practical good sense characteristic of the author Correctly assuming that recent insanity in very many cases is a curable disorder, Dr Blandford proceeded to discuss the question, whether recovery will be likely to take place only under asylum supervision, or is there a fair chance of curing the sufferer in a private house or the house of a medical man? In this country, and in recent years especially, it has been urged as a maxim that the earlier cases of admitted insanity can be removed to an asylum for treatment, the better is the prospect of their recovery And Dr Blandford readily admitted that, "for the great majority of patients asylum treatment is the only available method," while he claimed a certain proportion of insane persons whom it was important to treat, if possible, outside of an asylum In specifying this class of cases thus desirable to treat without legal adjudication or assignment to an asylum, he mentioned females of high rank whose friends are reluctant to apply for the necessary certificates, young persons of both sexes whose confinement in an asylum would constitute a great barrier to their getting employment after their recovery, and sometimes mar their prospects for life, cases of maniacal excitement or acute mania, caused by the use of alcoholic or other anæsthetics, or by mental excitement in subjects of a highly nervous or hysterical temperament, and many cases characterized by little excitement, and only such delusions as are harmless in their tendencies

It may be questionable whether Dr Blandford did not allow too much influence to the popular prejudice, or so called *stigma* supposed to be incurred by treatment in an asylum The fact of having been treated in an asylum for insanity undoubtedly operates as a hindrance, in some degree, to subsequent employment and the attainment of certain social relations so far as such fact is known But does not the detriment to the individual come from the fact of having once been insane, and the fear on the part of friends and employers that the same might recur, at any time in the future, rather than from the fact of whether he had been treated in an asylum or in a private house? The chief practical questions would seem to be, in determining the proper course of treatment for individual cases, are, *first*, as to the probable duration of the derangement, *second*, as to the ability to command the necessary medical attendance with thoroughly judicious nursing, and, *third*, the occupancy of such rooms as admit of the reasonable seclusion and safety of the patient That there are constantly occurring cases of acute insanity arising from temporary causes, which would recover in from one to six weeks, under the control of a judicious physician and two quiet, faithful nurses and the exclusion of interested and excitable friends, better without removal to an asylum than with, has been demonstrated within our own observation We are satisfied that in this country there is not sufficient attention given to the proper discrimination in this respect, and too uniform a tendency to send all cases to asylums, either public or private Dr Blandford's address is timely, and will have a good effect upon the profession generally

MASSAGE AND METHODICAL EXERCISE

The increasing experience with massage, and the appearance of several good books on the subject have given an impetus to the study of massage and methodical exercise that is gratifying In short, there seems to be a tendency in more recent therapeutics which leans towards a decreased use of drugs and an increased observance of the laws of hygiene, in the broadest sense, and in so far as the use of mechano therapy is concerned this is really going back to the first principles of the medical art In fact, an intimate connection may be traced between the revival of medical gymnastics, or muscle exercise for the purpose of healing disease, and the revival of the ancient gymnastics as a part of the necessary education of the body, though the revival of the former took place at an earlier date Hoffman wrote more wisely than he knew, perhaps, when he said in

the early part of the last century "Medicine will never progress until we apply the laws of mechanics and hydraulics" But it was not until a century after this that the Swede, Ling, reestablished the gymnastics of the ancients on a scientific basis, and became one of the first to elaborate a complete system on anatomical and physiological grounds The system gradually found adherents, until in 1876 von Mosengeil published in Langenbeck's *Archiv* the first complete and scientific treatise on mechanical manipulations physiologically considered

The most recent, and one of the ablest of the contributions to this subject is "Massage and Methodical Muscle Exercise," by Dr J Schreiber, director of the Sanitarium Alpenheim, in Styria, the book has been well translated by Dr Walter Mendelson, of New York, and is issued by Lea Bros & Co, of Philadelphia Schreiber has given in this work such a clear exposition of the whole subject, and so little general attention has been paid to it in this country, that a general analysis of the work may be interesting to our readers

As with many scientific practices, in the movement-cure empiricism preceded scientific demonstration It is now time, however, that empiricism be wholly excluded from the practice of massage, movement-cure, or mechano-therapy, as we may choose to term it In order to understand the action of mechano-therapy it is first necessary to know something of its physiological effects The primary (purely mechanical) effects consist in the removal of lymph, exudations, transudations and extravasations, the destruction of exudations by pressure, the removal of vegetations by frictions, and the solution and removal of adhesions The secondary effects act by increasing the circulation, by stimulating the muscular and nervous systems, by setting up molecular changes, and producing consequent changes in sensation, and by affecting alterations in the processes of general nutrition Inasmuch as mechano-therapy, by removing an exudation causing pain, may relieve pain it may be fairly claimed as an analgesic, and as the manipulations empty the lymphatics, and cause tumefaction, heat and redness to disappear, an antiphlogistic effect is produced, and as an accumulation of fluid may be prevented or removed it is plain that mechano-therapy has the power of causing resorption In regard to the secondary effects, there is a physiological theorem of great importance for the proper understanding of the subject, and one which is of practical application in the treatment of neuralgias "Any source of energy conveyed to a nerve from without first expends itself in producing molecular change, and this is again converted into energy manifesting itself through the various forms of innervation" But as yet we do not know the nature of the translation of this molecular change into nervous energy Of the chemical changes during nervous activity we know less than of muscle metabolism, but the more we know of these the more easily will we understand the as yet obscure points in mechano therapy

That systematic exercise is one of the best means of preserving and restoring the proper balance in the distribution of the blood in the body is recognized by all physicians Local hyperæmias can be made to disappear by exercise, as all brain-workers know Sommerbrodt has shown that in all exercises which increase intra-bronchial pressure, as singing, laughing, rowing, swimming, etc, the effects produced on the circulatory apparatus are diminished tension of the arterial walls, increased cardiac action When the exercise ceases the arterial tension rises again, and the heart beats slower Through its action on the circulation and heart active muscular exercise has distinct effects on the skin and kidneys, on the deposition and removal of fat, and in fact on every function and tissue of the body Du Bois-Reymond pointed out in his excellent address on *Exercise* six years ago that muscular exercises are really more exercises of the central nervous than of the muscular system, that they are especially exercises of the brain and cord, and that all species of bodily exercises are not simply muscular gymnastics but nerve gymnastics too This fact will be especially appreciated by those who have seen the beneficial effects of regular muscular exercise upon the insane, and upon anæmic and overworked girls By muscular exercise, too, we cultivate the sensory and the mental function as well as the motor nervous apparatus, especially when the exercise consists of complex movements And Johannes Muller made an observation which strikingly confirms the truth of what Du Bois-Reymond says, and upon the recognition and utilization of which the gymnastic treatment of chorea depends that perfection in bodily exercise consists often as much in the suppression of useless movements as in the acquirement of those desired

---

In regard to the treatment of disease by mechano-therapy, a subject of special interest to the practitioner, Schreiber says that mechano therapy, in accordance with its physiological effects, will be successful where it is desired to produce the following results

1 To cause an increased flow of blood to the muscles and soft parts, increasing thereby the circulation and removing accumulations of the waste tissue, whose retention causes various disturbances of function To strengthen muscular fibres, and by setting up molecular vibrations to induce changes, not only in the muscle and nerve fibres, but perhaps even in the nerve centres themselves

2 To cause the resorption of exudations, transudations, and infiltrations in such organs as are accessible To effect the separation of adhesions in tendon sheaths and joints, without recourse to the knife To remove, by grinding away, intra arthritic vegetations (Direct effect)

3 To increase, by passive and active exercise of all the muscles, the oxidizing effect of the blood, in this way correcting disturbances in its composition, and stimulating all the vegetative processes

4 To relieve the congestion of such internal organs as the brain, lungs, intestines, uterus, kidneys, etc., by increasing the flow of blood to the muscles

5 To stimulate directly the sympathetic nervous system, thus increasing secretion, and reflexly the activity of unstriped muscle fibre, and so relieving various functional derangements

6 By systematic exercise (health gymnastics), to educate morbidly affected muscles, to convert abnormal into normal actions, and to suppress useless movements

---

In his section on the mechanical treatment of neuralgias and muscular rheumatism Schreiber emphasizes the fact that a diagnosis between the two affections is not always easy, as they frequently coexist In claiming good, and even brilliant results for mechano-therapy in this field, he bases his claims only on long standing cases that have resisted all other means

In regard to the mechanical treatment of chorea it is interesting to note that Laisné, after numerous observations, concluded that 1 None of the means hitherto employed against chorea can show such uniform success as gymnastics 2 The mechanical treatment is applicable to almost all cases, whereas the medicinal very frequently is not 3 The improvement begins as soon as when sulphur baths are used, while the sedative action usually manifests itself within a few days 4 With the arrest of incoordinate movements, the general health of the child markedly improves, so that not only the chorea, but the accompanying anæmia is cured as well

---

AN ERROR —In a previous number of THE JOURNAL, p 407, we announced the death of Dr Richard Quain, of London, as we found it in the daily secular press From a recent number of the *British Medical Journal* we learn that it was Mr Richard Quain, a cousin of the eminent anatomist, who died at the advanced age of 87 years, while Dr R Quain remains in good health

---

THE AMERICAN PUBLIC HEALTH ASSOCIATION, will hold its fifteenth annual meeting at Memphis, Tenn , on Tuesday, Wednesday, Thursday and Friday, November 8, 9, 10 and 11, 1887, in Young Men's Hebrew Hall, corner of Union and Second streets Dr G B Thornton, of Memphis, Tenn , is Chairman of the Local Committee of Arrangements, from whom all needed information concerning railroad fares, hotels, etc , may be had

---

SOCIETY PROCEEDINGS

PHILADELPHIA COUNTY MEDICAL SOCIETY

Special Meeting, September 19, 1887

THE PRESIDENT, J SOLIS COHEN, M D, IN THE CHAIR

DR F W PAVY, F R S, of London, addressed the Society upon

SOME MORBID CONDITIONS OF THE URINE

I am before you to say a few words upon certain morbid conditions of the urine, and my hope is that we may compare notes of observations in the old world with observations in the new world I shall first of all refer to albumin Albumin in the urine with us was formerly regarded as a matter of the most serious import, but we are now beginning to recognize that a certain amount of albumin in the urine is not always of grave import My own practice lies very largely with urinary diseases, and patients coming under my care always have the urine examined by an analyst, and I am frequently meeting with a certain amount of albumin in the urine, without its presence being attended with anything that would lead me to suspect that a grave condition exists In association with diabetes, it is not at all uncommon to find, when the patient first comes under observation, a certain amount of albumin in the urine, but when the patient is put under treatment for the diabetes, it is not infrequently found that the albumin disappears in the course of a few weeks In these cases of albumin in the urine, we must look to the general condition of the patient to see whether or not there are other indications of the existence of grave renal disease

There is another condition which I presume has been brought before the profession in America, in which albumin exists at a certain time of the day, and not at others I have suggested for this condi-

tion the term *cyclic albuminuria* I have studied these cases for some years past, and I should think that they occur in this country as well as in the old world I know that they occur in Germany, for the matter has been taken up there and followed out This condition is observed in persons who are excitable and of a nervous disposition, and as a rule in young persons, although I have met with some cases in the middle-aged The albumin is to be met with at one time of the day and not at others These cases are recognized, as it were, only by accident Sometimes the urine is examined on account of some pain in the loins, but most frequently these cases are discovered through examinations for life insurance purposes, or for some branch of the civil service, as is required by the Bank of England So long as the individual maintains the recumbent posture, no albumin will be detected, but in one and a half or two hours after rising the maximum quantity of albumin will be found As a rule, the quantity of albumin declines toward evening, and on going to bed it has entirely disappeared Sometimes a trace of albumin is to be found in the afternoon and evening, but the first urine passed on rising in the morning contains no albumin whatever These cases seem to be of no serious import I suppose that the presence of albumin depends on the condition of the vessels I suppose so, but certain it is that these cases are not associated with any constitutional condition I now come across quite a large number of them

I shall next refer to *sugar in the urine* This is another morbid element which has varying degrees of importance In young persons it is of the gravest import, while in elderly persons it is not so serious In early life I have known cases to go on for years, but this is the exception, the usual duration is about two years Ultimately they all terminate unsatisfactorily After the middle period of life, however, sugar in the urine has a very different significance In young subjects we have a disease which seems to be of a progressive nature Notwithstanding whatever we may do for it, there is something which insidiously progresses in the system and leads ultimately to a fatal termination But after the middle period of life a good deal depends upon the patient himself Under proper management the disease may, as a rule, be held under control and the patient live for years in a satisfactory condition, but to accomplish this, rigid measures of treatment must be carried out

One may express in a very few words, and without advocating any idea or theory, the precise nature of *diabetes mellitus*, or sugar in the urine I should speak of it as a defective or faulty assimilative action—a faulty chemistry The elements of the food which we take undergo chemical change in the system, by which they are rendered useful A certain group of principles entering largely into the composition of our food, are the carbohydrates These principles in diabetes do not undergo their proper chemical change and thus become eliminated from the system What do we observe in a state of health? A person takes one of the carbohydrate group, it makes no difference which—starch, grape sugar, cane sugar, dextrine, or sugar of milk—they all behave alike in the system, and it is so changed as to be rendered subservient to the requirements of the system In a state of health, we see nothing more of them Not so in diabetes In the diabetic these carbohydrates are no longer consumed There is a faulty disposal of them Received into the alimentary canal and afterward absorbed, they do not undergo their proper transformation, but pass off from the system in the form of sugar in the urine, so that I say, looking at these two conditions, a condition of health and a condition of diabetes, we may describe diabetes as a faulty disposal—a faulty transformation or assimilation of the carbohydrate elements of our food In diabetes, in proportion as these carbohydrates are taken, so will be the amount of sugar in the urine This I can say without any hesitation whatever

In order to follow a case of diabetes satisfactorily, I consider that a quantitative examination of the urine should be made, and, for myself, I feel quite in the dark as to the progress of a case unless I have this quantitative examination In my own practice, I keep an analyst who examines the urine of patients—a night and morning specimen—and directly I get the analytical report, I can read off exactly the condition that I have to deal with Without this I should be perfectly in the dark as regards the progress or the severity of the case It does not do to rely on the specific gravity I have met with a specific gravity of 1 040, without any sugar in the urine Medical men are often concerned over the specific gravity of the urine The patient may have been put under treatment, but still the specific gravity keeps up to 1 032 or 1 035, although the urine is free from sugar Under these circumstances, I say to the medical practitioner Do not concern yourself with the specific gravity If the urine is free from sugar, the high specific gravity is a favorable sign, as showing that the kidneys are equal to good work If the kidneys were diseased, there would be a low specific gravity The high specific gravity may be kept up by the passage of only a limited quantity of water, and by the nitrogenous diet which the patient is taking, adding to the elimination of urea On the other hand, a low specific gravity may sometimes be met with where there is a considerable quantity of sugar in the urine I have met with a specific gravity of 1 009 or 1 010, and yet the urine contained a considerable quantity of sugar These have been mixed cases of diabetes insipidus and diabetes mellitus They are proven to be mixed cases by the fact that when the patient is put under proper dietetic treatment, the sugar disappears, but the quantity of urine keeps up I myself do not attach so much importance to the specific gravity as is done by certain medical men

In testing the urine for sugar, my opinion is that the copper test is by far the best As we all know, Fehling's solution is the test generally employed, but there is this disadvantage about the Fehling's solution, it does not keep well, after being kept some time, it throws down a precipitate without the

presence of sugar This had led to many mistakes in diagnosis I have frequently had patients sent to me with the statement that they were suffering with diabetes mellitus, when the only trouble was that a faulty Fehling's solution had been employed Some years ago, I directed my attention to the question whether or not the ingredients of the Fehling's test could not be put together in the form of a pellet, and the solution be made as required Certain difficulties were experienced at the outset, but these have been overcome The pellets, as now made, consist of sulphate of copper in the anhydrous form, Rochelle salt, and potash It is necessary to separate the sulphate of copper from the potash This is done by first putting in the die the sulphate of copper, then a little Rochelle salt, next the potash, and, finally, more Rochelle salt The pellet, after being made, is surrounded with waxed paper and kept in a well stoppered bottle If properly prepared and handled with care, the cork not being left out of the bottle, these pellets will keep indefinitely There is this advantage about the pellet—it will never deceive you, for if it is allowed to absorb moisture, it at once becomes unfit for use, the oxide of copper being thrown down in the form of a black precipitate

In the treatment of diabetes, I attach the greatest importance to diet I do not consider that you can get on with the management of these cases unless you exclude as far as possible those principles of which there is a faulty assimilation If sugar appears in the urine, it must previously have existed in the blood I know from frequent examinations that the blood contains a *trace of sugar*, which may be represented in figures as from 0 5 to 0 8 part per 1000 In harmony with this condition of the blood, there has been a trace of sugar in the urine

The ammonia cupric test is the one I employ as a quantitative test It consists of Fehling's solution with the addition of ammonia With the Fehling's solution there is, on the addition of saccharine urine, a precipitate of the suboxide of copper, and, for quantitative purposes, this precipitate interferes with the determination of the exact time when complete reduction has taken place While the presence of ammonia does not interfere with the reduction, it keeps the reduced suboxide in solution, and we get the decoloration without the formation of any precipitate whatever The addition of ammonia gives a more intense blue color to the Fehling's solution, and this is brought by the reduction to the color of water without the formation of any precipitate With the apparatus in perfect order, the quantitative determination can be made in two or three minutes This test is so delicate that ordinarily, to perform it satisfactorily, you have to dilute the urine 1 20, and where it contains much sugar, 1 40 I usually determine the proportion of sugar per thousand of urine, but if it is desired to determine the number of grains per ounce, this can be done by multiplying the quantity per thousand by 0 4375

In examining the urine of a diabetic, I generally desire that a night and a morning specimen be brought When a person lives as people ordinarily live in England—that is to say, taking a meal on rising in the morning, breakfast, a meal in the middle of the day, lunch, and a meal in the early part of the evening, dinner—the urine passed on going to bed contains considerably more sugar than the urine passed in the morning When a person dines in the middle of the day and sups shortly before going to bed, then the conditions are reversed—there is less sugar in the night water than in the morning water Over and over again, by the quantitative examination of the urine, I have detected errors of diet where the patients have had the greatest desire to keep to what was right A person who has been passing only a little sugar, brings a specimen which contains a large quantity of sugar Under such circumstances we must look for some error in the preceding meal In one case this proved to be blanc mange which had been made with corn flour Blanc mange for the diabetic should be made with cream and gelatine or isinglass In another case a patient had been passing very little sugar, when suddenly the quantity increased Careful questioning revealed no error in diet, until it was learned that the patient had substituted for the bran biscuits which he had been using others said to be "just as good," which examination showed to be made of the whole meal I refer to these cases to show the value of the quantitative analysis

In the treatment of these cases, the exclusion of the carbohydrate elements of the food should be as complete as possible In the case of a person in the middle period of life, I first put the patient upon a strict diet Very often the sugar for a time lingers in the urine It is materially diminished, but has not disappeared I may also say that I have, in addition, recourse to opium, codeia, or morphia, for I believe that these drugs have an important influence in controlling the disease—or, to put it in other words, they restore the assimilative power Certain it is that under the influence of these drugs and strict diet, sugar after a time disappears from the urine, and after the urine is kept free from sugar for a few months, I find that the individual has a certain amount of assimilative power over the starch of bread I test this by giving him a couple of ounces of bread Frequently there is no reappearance of sugar If there is no return after this has been continued two or three weeks, I increase the quantity to three ounces per diem Then, if there is no return, to four and one half ounces, and finally, to six ounces Then the person is in the position of a small bread eater I recommend persons to be content with that They can very well give up potatoes and sugar, but to give up bread is a serious matter with many people When a person can take six ounces of bread per diem he is not in an unfavorable condition Many of these persons can continue to take this quantity of bread with no return of sugar in the urine If, however, they go further and resume their ordinary diet, there will be a reappearance of sugar The urine must be taken as the guide Treating the case in this way, my experience is that, after the middle period of life, these patients do exceedingly well

I must apologize for the crudeness of these remarks, for I have had no time for preparation I thank you most heartily for the attention which you have given to me I cannot close without thanking you and your countrymen for the cordial reception given to myself and my confrères by everyone with whom we have come in contact

DR JAMES TYSON said It is needless to say how much indebted we all feel to Dr Pavy for his remarks, and in the brief time allowed for discussion I desire first to say that I think we, in America, have passed through much the same transition in our views as to the import of albumin in the urine as has taken place in England The fact is thoroughly recognized that albumin may be present without any serious import, but the explanation of these curious albuminurias is still unsatisfactory There are a certain number of them which are clearly the result of diet, and may be called alimentary albuminurias, but that all cases cannot be thus explained is shown not only by the cases alluded to by Dr Pavy, but also in such as those where the urine on rising is free from albumin, but in which within an hour afterward the urine passed is albuminous, although no breakfast has been taken The crucial test for the determination of the gravity of an albuminuria is the presence or absence of casts I have found that in these harmless albuminurias tube casts are invariably absent, and where there is a constant association of albumin and tube casts, it, of course, means renal disease, no matter how slight the general symptoms may be

With reference to sugar, we also entertain much the same views In my hands Fehling's solution has proven the most satisfactory test, although open to the disadvantages alluded to by Dr Pavy Much, however, may be done to preserve it, if the bottle is kept corked and in a dark place, the solution will keep for a much longer time I have also obtained satisfactory results in this respect from a Fehling's solution in which mannite was substituted for the tartrate of potassium and sodium I have found that the pellets made in this country rapidly spoil

In reference to the treatment, we largely agree I am inclined to believe that certain sugars, and especially certain fruit sugars, are better managed by the diabetic than are others Thus, I think that a patient may eat an apple, or even an orange, without much disadvantage, whereas the use of grapes is always attended with an increase in the quantity of sugar The same is true of milk sugar I am satisfied that milk is a good diet for most diabetics, although, of course, it is not a cure The dietetic treatment is, for the most, efficient, but, so far as my experience with drugs goes, I am satisfied also that the preparations of opium, and especially codeine, are the most efficient adjuncts to the dietetic treatment They are, however, open to the objection that they produce constipation, which almost always aggravates the other symptoms of diabetes

DR J W HOLLAND said The remarks of the previous speaker have reminded me of my experience with glycerine as an organic medium in Fehling's solution This makes a solution which keeps for a considerable time, although not indefinitely At the Jefferson College laboratory we employ two solutions of definite strength, one containing the sulphate of copper, and the other Rochelle salt and the caustic potash or soda These are mixed in equal quantities when it is desired to employ the test

In the use of Dr Pavy's quantitative test, I find one small objection—which can be obviated by extreme care—that is, if the solution is boiled in an ordinary capsule the ammonia will be driven off and reoxidation of the copper follows If a flask is employed the ammonia will not escape so rapidly

One form of pellet lately brought to my attention is the indigo carmine pellet This seems to keep indefinitely It is composed of sodium carbonate and the sulphindigotate of sodium It is a very sensitive test—even more sensitive than the Fehling's solution

Dr KLEEN, of Karlsbad, was introduced, and said I had, two years ago, under my care at Karlsbad, a most singular case Mm X, of Gothenburg, fifty years old, then consulted me, telling me she was suffering with diabetes that the illness had accidentally been discovered the year before and that she had then visited Karlsbad (1884) and consulted Professor Seegen (who since that time had retired from practice)

Mm X when I saw her, presented no symptoms of diabetes or of any other illness, except some nervous debility I gave her a considerable quantity (100 grams) of cane sugar, collected the urine for some hours, and afterward for twenty-four hours, but found no glucose in it I did not succeed better after she had dined copiously on rice and other amylaceous food I then pronounced her free from diabetes I still kept the case under observation, however, and at last found, upon examining the urine two hours after a meal, which had ended with a large portion of sweet fruits (mostly pears), a small quantity of reducing substance Both Fehling's and Nylander's (bismuth) solutions showed reactions corresponding to the one we got, with urine containing 0 1–0 2 per cent of glucose When testing the urine with polarization by the spectroscope, I found, to my utter surprise, a slight deviation *to the left* The urine did not contain a trace of albumin I was at a loss what to think of it, and submitted it to the test of fermentation The same day, however, I received a letter from Professor Seegen, stating that when the patient was under his care, her urine had contained much larger quantities (as much as 3 per cent) of reducing substance, and that he had found that substance to be *levulose* At the same time Professor Seegen sent me a supply of glucose, asking me to submit the patient to a test of her toleration of that substance So I did, and found that portions of 100 grammes or more did not produce more than very small quantities of reducing substance in the urine—that substance, to judge from a very slight deviation to the left in a good instrument, being levulose

Worm-Müller has proved that glucose, administered in large doses, passes to a certain (small) por-

tion unchanged into the urine, even in healthy persons, while it passes to a much larger proportion into the urine of the diabetic patient He has also found that all the different species of sugar, administered in large doses, in a certain (small) proportion pass *unchanged* into the urine even of healthy persons, while in the diabetic patient at least some portion of them passes into the urine *tranformed into glucose* He believes in this latter circumstance to have found a difference, also, between persons suffering from real diabetes and those whose urine, while under ordinary diet with the common reagents, presents traces of glucose or only now and then, under peculiar circumstances and in a passing manner, contains somewhat larger quantities of it

This coincides with my own experience so far as it hitherto goes Like all physicians who occupy themselves with researches in this direction, I find every year persons whose urine shows traces of sugar, and now and then—especially after strong emotions, after alcoholic excesses, or after very rich meals of rich food (but, generally, not after meals *exclusively* consisting of amylacea or of cane sugar) —in a passing manner, somewhat greater quantities of a substance which shows *all* the qualities of glucose In these doubtful cases, I usually give a large quantity of cane sugar, and afterwards often find no glucose—or only slight traces of it—in the urine, till I have boiled it with mineral acid, and thus converted a portion of the cane sugar that has passed over into glucose, whereupon I will find the well-known reaction of glucose I consider these cases to be distinct from true diabetes, though it seems to me highly probable that they indicate a tendency to that disease, which others of larger experience than myself have also noticed—for instance, Professor Frerichs

In the present remarkable case of levulosuria, I found that some portion of cane sugar passed unchanged into the urine It seemed to me to be of great interest to find out how Mm X reacted against the other species of sugar, especially against levulose, which, with some reason, could be expected to pass over in larger proportion than in quite normal persons I therefore had the wish to administer a large amount of honey (which is a mixture of glucose and levulose), and also to make a test with milk sugar, but Mm X, who had heard that she should avoid sugar above all things, and who had an interest in her own case, only partly of the same nature as my own, did not wish to be submitted to further experiments, especially as I could not promise that they would be without some momentary influence on the urine I can, therefore, only give the above description of the case, such as is already given by Prof Seegen, who first discovered it, but I am not without hope of being able in the future to give fuller information upon it

I am decidedly of the opinion that the case is not, clinically speaking, strictly one of diabetes If the substance had been glucose, it would have ranged among the large number of the above named glucosurias, continuing unchanged for a great number of years in healthy or nearly healthy persons I was rather astonished at seeing Professor Seegen state that the urine once contained as much as 3 per cent of levulose, but cannot doubt the accuracy of this most excellent observer That the quantity has diminished so very much without any dietetic treatment, makes the case even more interesting than it otherwise would be I allowed Mm X a tolerably good supply of starchy food, advised her only to avoid excessive use of them, and I have lately heard that the urine only now and then contains small quantities of reducing substance

AMERICAN GYNÆCOLOGICAL SOCIETY

Twelfth Annual Meeting, held in the Hall of the Academy of Medicine, New York, September 13, 14 and 15, 1887

(*Continued from page 505*)

SECOND DAY—MORNING SESSION

The President in a few remarks called attention to the death of Dr John Scott, of San Francisco, Cal, and appointed Dr Thomas Addis Emmet to prepare a memorial for the published Transactions

DR C D PALMER, of Cincinnati, read a paper on

THE THERAPEUTIC VALUE OF SOME MEDICINES IN THE TREATMENT OF HÆMORRHAGIC CONDITIONS OF THE UTERUS

The author referred to the fact that very few papers on the medicinal treatment of hæmorrhagic affections of the uterus appeared in the eleven volumes of the Transactions of the Society In hæmorrhage from the uterus, it is important to remove the cause where this can be found The object of the paper was to speak of the value of certain internal remedies and their field of utility

No drug is more frequently used than *ergot* This is beneficial in many cases, but may aggravate some It is of service in chronic hyperæmia and in subinvolution Its effects are less marked in nulliparæ than in multiparæ In the treatment of uterine fibroids, between the use of galvanism and of ergot, the field of laparo hysterectomy must be a limited one The hæmorrhage from fungoid degenerations and from ovarian irritation is better met by other remedies In some cases of pelvic peritonitis and pelvic cellulitis, the hæmorrhage has been increased by use of ergot

Digitalis in appropriate cases is of service It is reasonably reliable in uterine hæmorrhage due to cardiac trouble In atonic conditions of the circulation, weak heart and low arterial tension, which tend to induce passive hyperæmia, digitalis may be used

Cannabis Indica has been the subject of diverse claims The drug varies much in strength It acts more especially on the nervous system Its indications are imperfectly defined and its effects uncertain

Bromide of potassium is useful in certain hæmorrhagic states It is indicated where there is sexual excitement and ovarian congestion and irritation

It is not so useful where hæmorrhage is due to uterine irritation, although in some cases of fibroid tumor the author had found it more useful than ergot

Arsenic is of service in uterine hæmorrhage It is not prompt in its action, but in appropriate cases it is effective It acts as a tonic, stimulating all the functions, and especially those of the skin and mucous membrane In chronic endometritis, with or without fungoid degeneration, a course of arsenic will be of material service It is of value in the case of young girls when menstruation appears too frequently and continues too long In menorrhagia at the time of the climacteric it is of service, although its effect is less decided than in the former group of cases Arsenic is a good remedy in menorrhagia of malarial origin

Gallic acid is the best representative of the astringent class of remedies, and has been repeatedly tested in hæmorrhage due to uterine atony Its large dose, unpleasant taste and tendency to disorder digestion limit its use

Active cathartics, particularly so-called cholagogues, as mercury, are useful in uterine hæmorrhage of hepatic or splenic origin

Viburnum prunifolium, hydrastis and gossypium have been recommended Dr Garrigues has reported 139 cases of uterine hæmorrhage form various affections in which he used gossypium with the result of relieving the hæmorrhage in 125 cases

The last remedy referred to was hamamelis virginiana If thoroughly tried this is usually efficacious The author had used this drug with satisfactory results for six or eight years It is not equally potent in all cases of uterine hæmorrhage For active, profuse hæmorrhage, it is inferior to ergot, but for slight, long-continued flux, when the blood is dark and venous, the hæmorrhage being passive in character, it is the remedy *par excellence* The best preparation is the officinal fluid extract in doses of a few drops to 2 drachms None of the remedies here mentioned were intended to supersede local medication where indicated

DR FORDYCE BARKER, of New York, remarked that every one of the remedies mentioned is of special value in certain cases, and success in treatment depends upon a careful selection of the cases Arsenic is useful when the system is broken down and the patient is approaching the climacteric Where the hæmorrhage continues and is profuse, the most valuable remedy is the fluid extract of hydrastis combined with fluid extract of hamamelis, ½ drachm of each being given He had used viburnum prunifolium largely in passive hæmorrhage occurring at an early period of gestation, and in threatened abortion

DR LLOYD ROBERTS, of Manchester, Eng, had very little confidence in any drug except ergot in the treatment of uterine hæmorrhage The great point in the use of ergot is to get a good preparation In cases of hæmorrhage at the menopause when the uterus is flabby, and in the case of young girls, the best results are obtained by giving it in the intermenstrual period

DR W BAILS-HANDLEY, of Melbourne, could not see how the remedies referred to are going to act in restraining hæmorrhage If their use is to be supplemented by operative measures, it is hard to say what does the good He had given ergot in fibroid tumors, but could not say that he had had the slightest benefit from its use

DR J A D GRANT (Bey), of Cairo, Egypt, said that two years ago he was called by a doctress to see a patient There was a tumor, and uterine hæmorrhage recurred every ten days The case had previously been diagnosed as fibroid tumor and removal of the ovaries recommended There was a history of syphilis, and as hæmostatics had been thoroughly tried for months, he decided to use mercury Stimulants and cinchona bark were also given The hæmorrhage ceased and the tumor, which was as large as a child's head, gradually diminished in size, and in three months the woman was able to return to work

DR H P C WILSON, of Baltimore, remarked that when he excluded cases of submucous fibroids, cases of granulations and cases of polypi, the number of instances of uterine hæmorrhage is very small He had very little confidence in any remedy as a hæmostatic in these cases

DR JAMES R CHADWICK, of Boston, referred to the value of turpentine He had used this in hæmorrhages from all causes with surprising results Ergot given between the flows is of more service than when given during the hæmorrhage During the flow he is in the habit of giving aromatic sulphuric acid

PROFESSOR DOLERIS, of Paris, France, made some remarks on

ALEXANDER'S OPERATION

He treats cases of retroversion of the uterus by shortening the round ligaments, where all other measures of treatment have failed Where there is retroflexion, he first overcomes the flexion by three or four forcible dilatations and then shortens the round ligaments In cases of prolapse, he first restores the uterus to a normal condition If the cervix is abnormally long, it is amputated and the round ligaments are then shortened Anterior and posterior colporrhaphy are also performed In cases of anteversion, there is no need to shorten the round ligaments, as the pressure of the abdominal contents does not come upon the uterus as in the case of retroversion In these cases the vaginal operation is sufficient The object of shortening the round ligaments is not to suspend the uterus, but to antevert it

DR WM L REED, of Glasgow, said that one of the most important points to which attention should be called is that even when a successful operation has been performed in a case of chronic retroversion, you must not expect the patient to feel quite well in the course of a few weeks All that the operation does is to restore the position of the uterus, it does not alter its condition The patient will probably be no better three months after the operation than before it, especially if care is not taken The after-treatment is most important If you take a case of prolapse with the uterus down to the woman's knees, shorten the ligaments and allow her to be about in

two weeks, you need not be surprised if the trouble is soon reproduced The patient should be kept in bed five or six weeks, and afterwards should wear a well fitting pessary for five or six months A pessary that before the operation could not be kept in place one hour will remain without difficulty after the operation

Dr A Martin, of Berlin, had not performed this operation, but should not object to performing it when a suitable case presented itself His experience led him to believe that we exaggerate the importance of prolapse He had seen many cases where the patient suffered this displacement without discomfort He did not think that an operation on the ligaments without restoration of the pelvic floor will give a certain hope that the uterus will be retained within the pelvis In these cases he performed Hegar's operation

Dr C C Lee, of New York, had done Alexander's operation about 19 times The operation is indicated in those cases where a pessary cannot be borne on account of the abnormal tenderness of the vaginal vault, although no distinct pelvic peritonitis or cellulitis can be detected It may be used in cases of retroversion of the uterus with chronic salpingitis which cannot be cured without laparotomy It is also to be employed in a limited class of cases where there is complete procidentia and where the usual plastic operations have failed to keep up the uterus

Dr Howard A Kelly, of Philadelphia, had done this operation for three years It is folly to expect a heavy uterus to be held over a large open canal by two ligaments If the cervix is hypertrophied it must be removed Suitable operations should be performed in the vagina. In the case of a heavy uterus the round ligaments, acting at right angles to the organ, are at a disadvantage when we attempt to raise the womb In one case, therefore, he had substituted hysterorhaphy with entire success

Dr Alexander J C Skene, of Brooklyn, then delivered

THE PRESIDENT'S ADDRESS

He first referred to the organization of the American Gynelogical Society, which occurred in the Hall of the Academy of Medicine, New York, twelve years ago The Society has passed its age of development and entered upon its period of growth The major portion of the time of this Society has been given to surgical subjects This should not be so As much attention should be elicited by the discussion of a functional affection as by the report of a case in which the surgeon has removed all the organs of the body with the exception of those absolutely essential to life There is room for more definite knowledge with reference to pathology and especially with regard to nomenclature There are still interesting fields to be explored and the greatest of these is with reference to preventive medicine Gynecology has much to accomplish in this direction Brilliant reputations have been made by the removal of the tubes but little has been done in the way of preventing the diseases which lead to their destruction In the present state of society more honor is accorded him who relieves the ills of man, than is given to the one who prevents them In obstetric medicine greater advances have been made in this direction Vesico vaginal fistula, which formerly were very frequent, have almost entirely disappeared under modern methods of obstetric procedure

Progress in gynecology would be hastened by improvement in the medical press In this country there is too much writing in proportion to the amount of thinking and practice *The most copious writers are not the most distinguished in practice*

Dr George Granville Bantock, of London, read a paper on

THE TREATMENT OF THE PEDICLE IN SUPRA VAGINAL HYSTERECTOMY

The surgical treatment of fibroid tumors of the uterus, has attracted a great deal of attention during the last ten years Considerable progress has been made in the last three years, mainly in the treatment of the pedicle In his first operation the speaker ligatured the pedicle, applied the cautery, split the pedicle into an anterior and posterior portion and brought these together with sutures The patient died four days later of septic poisoning It is a peculiarity of uterine tissue that it shrinks under strong pressure In this case the ligatures soon became loose and there was oozing into the peritoneal cavity In the next case the pedicle was tied in three portions and surrounded by a silvered copper wire and transfixed with two long needles It was brought into the lower angle of the wound Thirteen hours after operation there was a free flow of blood, which was arrested by the cautery On the ninth day, as the copper wire did not make sufficient pressure, a wire écraseur was substituted, and this succeeded in reducing the size of the stump As now performed the operation consists of surrounding the pedicle with a soft iron wire attached to a small écraseur by which the wire can be tightened Before cutting away the pedicle it is important to transfix it with needles to prevent the wire from slipping After the body of the uterus is removed, the pedicle is secured in the lower angle of the wound In some of the cases reported, the pedicle, which at the time of the operation was two or three inches in diameter, was reduced to one-third of an inch in diameter when the wire came off at the end of the eighteenth or twentieth day The author did not think the operation could be improvd by substituting the intra-peritoneal method of treating the pedicle Thirteen cases of pediculated fibroids treated by the extra-peritoneal method reeovered, while two treated by the intra-peritoneal method died

With reference to the after treatment of the pedicle, Dr Bantock said that if the pedicle is properly secured at the time of operation, the less it is interfered with the better The serre-nœud should not be touched in less than four or five days, unless there is oozing, in order not to disturb the adhesion of the peritoneum If there is bleeding it usually occurs within a few hours If the pedicle is thick, it may be necessary to tighten the wire When the

stump comes off the dry or wet method may be employed The former consists in dusting iodoform on the part The latter consists in washing the part with a solution of sulfurous acid, 1 9, and then applying equal parts of rectified spirits and glycerine

The author's statistics were as follows 57 cases of supra vaginal hysterectomy with 45 recoveries and 12 deaths In 5 of the fatal cases there was pronounced disease of the kidneys, in 1 there was acute enteritis, in 2 there was hæmorrhage, in 1 there was obstruction of the bowel, and in two septicæmia

AFTERNOON SESSION

DR JAMES B HUNTER, of New York, reported a case of *Acute Dilatation of the Stomach following Laparotomy*

DR A REEVES JACKSON, of Chicago, read a paper on

THE INTRA-UTERINE STEM IN THE TREATMENT OF FLEXURES

A large proportion of flexions of the womb do not need any treatment, others are wholly unamenable to treatment, while others are made worse by attempts at treatment The author began the use of the stem pessary in 1870 Previous to that time he had used dilatation of the cervical canal and incision of the cervical wall separately or combined The results were unsatisfactory All the cases thus treated relapsed The single symptom which was regarded as an indication for the treatment of a flexion was dysmenorrhœa

Details of the method—Having determined the presence of a flexion, a flexible olive-tipped bougie is introduced and allowed to remain from two to ten minutes according to the amount of irritation produced This is repeated at intervals of from one to three days The size of the bougie is gradually increased This treatment is continued until tolerance is induced, then, at the close of a menstrual period, a soft rubber stem, one third of an inch shorter than the uterine canal and of a size that can be readily introduced, is passed into the uterus and maintained in position by a tampon soaked with glycerine The tampon is renewed after two or three days and is repeated as long as there is any tendency for the stem to slip out This soft stem should be worn six or eight weeks when it should be replaced by a larger stem, and in six or eight weeks a still larger one As soon as the womb can be readily straightened a more rigid stem should be employed This should be of vulcanite The pessary should not be such as will stretch the internal os, but above this point, it may with advantage have a bulge In a few cases it was not found necessary to resort to the stiff instrument The hard stem is worn continuously for three months It is then removed for a week or ten days If there is then found a tendency to return to the former condition, the stem is again introduced and worn for another period of three months The essential principle in this plan of treatment consists in its gradual conduct The uterus must be coaxed and forced into proper shape Any method of treatment which involves the rapid removal of the flexion is dangerous and not liable to be of permanent benefit In no instance has inflammation followed the use of the stem When the flexion is maintained by adhesions or where there is evident inflammation, the stem is not to be employed The stem has been used by the author in 67 cases, 43 married and 24 unmarried 9 of the former had born children and 8 of the latter subsequently became pregnant 41 of the cases were cured, 5 improved and relieved of dysmenorrhœa and in 20 the result was not known

DR OGDEN, of Toronto, said that after the uterus is accustomed to the presence of a foreign body, the stem pessary is calculated to do a great deal of good To retain the stem in position he uses dry non absorbent cotton dusted with boric acid in preference to the moist cotton This can be left in three or four days

PROFESSOR LAWRENCE, of Bristol, Eng, stated that his plan had been similar to that of Dr Jackson He used the stem in selected cases where the only cause of the dysmenorrhœa is the bent condition of the uterus He related the following case A married woman aged 35 years, was sterile and suffered with dysmenorrhœa and inter-menstrual hæmorrhage After wearing the stem for two months the bleeding ceased and the dysmenorrhœa disappeared In six months he removed the pessary and the woman became pregnant

DR G APOSTOLI, of Paris, France, read a paper on

THE TREATMENT OF UTERINE FIBROMATA BY ELECTROLYSIS

The author described in detail the method of treating uterine fibroids, which he had recommended He had found electrolysis successful in checking the growth of the tumor and in decreasing its size He does not regard the plan of treatment as dangerous, having lost but 2 patients out of 200 cases, and in these instances death was not directly attributable to the operation He has also used this method for the relief of nervous pain in hysteria, employing the constant current, long continued This also relieves pain associated with effusion In 4 cases galvano puncture per vaginam has cured ovarian cysts after the treatment has been continued two years

Dr James R Chadwick, of Boston, read a paper on *Ventral Hernia after Laparotomy, and Its Surgical Treatment*

(To be concluded)

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, May 18, 1887

THE PRESIDENT, JOS TABER JOHNSON, M D, IN THE CHAIR

DR C V BOARMAN read a paper entitled

PUERPERAL TETANUS

(See p 522)

DR T E MCARDLE said that Dr T C Smith had recently, in another Society, reported a case following abortion, and that in the discussion which fol

lowed several other cases were mentioned, one of which followed childbirth

Dr W H Taylor inquired if the symptoms in this case were those of regular tetanus or of one form of puerperal fever? Were the spasms clonic rather than tonic? In short, are the symptoms the same as those of traumatic tetanus?

Dr Boarman replied that they were He has seen six cases of traumatic tetanus, and the symptoms in this case were just the same In fact, traumatism was probably the cause The patient was a well formed woman, but ergot had been freely given, three men had worked to deliver her At the end of the first day there were symptoms of puerperal fever which, however, lasted only a few days, when convalescence began At the end of the seventh day there were symptoms of approaching tetanus, and on the morning of the eighth day there was trismus, opisthotonos and the risus sardonicus The mind was clear

Dr W H Taylor did not think that this was the usual course pursued by puerperal tetanus Trismus is usual before opisthotonos In this case the patient was first dosed with ergot, but tetanus usually follows injury to the cervix Some days after this other symptoms followed, and for this reason he would hardly call this a case of puerperal tetanus The clonic spasm is not a necessary concomitant of puerperal tetanus

Dr J E Morgan in 40 years has seen but one case of puerperal tetanus, and that was about a year ago He was called by the gentleman in attendance and found the woman with tetanus He made only the one visit The woman died

Dr Kleinschmidt remarked that there was one factor in the case reported by Dr Boarman which made it interesting—viz large doses of ergot had been given What had this to do with the subsequent tetanus? It is well known that ergot will render the spinal column anæmic Possibly this is what happened in this case, and the anæmia continuing after the expulsion of the child, the spinal nervous system would be in a condition to explode after any peripheral injury Some authorities state that tetanus is not due to excitation of the spinal column, but to excitation of the sympathetic system In his opinion the sympathetic system is not as important as we are apt to think it, and at any rate, the sympathetic nerves have been traced to Clark's column in the spinal cord The sensory nerves of the uterus are of a low degree This dulness may explain the rarity of tetanus after an injury during labor, but with the spinal cord in an anæmic state, less irritation than usual was required to excite it into a fatal action

Dr Boarman said that the midwife gave probably about ℥ss of ergot during the night The womb was rigidly contracted, which accounted for his not being able to deliver He thought Dr Kleinschmidt's theory very plausible There was most likely abrasion by the instruments, and the tetanus was just as after any traumatic injury

Dr McArdle asked Dr Boarman how he accounted for the decomposition of the child and why, with a dead child, was Cæsarean section thought of?

Dr Boarman replied that the child was decomposed long before he saw it, and probably before labor began The fœtus was so rotten that in attempting to deliver, the whole arm, with the clavicle and scapula, came off in his hand The woman's people were not asked to choose between embryotomy and Cæsarean section, but they were told that either one of them had to be done and they very promptly forbade Cæsarean section

Dr S C Busey remarked that it was very fortunate that Cæsarean section was not done, as the woman would probably have died under it The improper administration of ergot makes the case especially interesting There are, however, many cases in which the drug has been administered improperly without being followed by tetanus, so if it was an agent at all it was a very remote one We have in this case the conditions usually causative, viz traumatism, perhaps not any more than is common after such manipulations, bad hygienic surroundings, and in addition a putrescent fœtus, puerperal fever in a few days and erysipelas in the immediate neighborhood Everything points to sepsis, and that he believes is the most common cause of tetanus We will have to fall back upon the theory that there is some individual idiosyncrasy which promotes tetanus He was glad to have Dr Kleinschmidt endeavor to account for the part played by the ergot, but we want some coincidences of puerperal tetanus and ergot before we can judge of its agency

Dr Kleinschmidt said that he admitted that the tetanus was traumatic, but he was trying to get the central nervous system in a condition in which slight excitation would produce it It was, he said, only *probable* that the ergot acted as he explained

Dr Boarman said that there was no room for doubt as to the nature of the case All the symptoms of tetanus were present Dr Busey's explanation of its cause was probably correct Schroeder makes the same statement The patient had been in labor long before he saw her, and her hygienic surroundings, at first, were of the worst, but he removed her, as soon as labor was over, to more airy quarters The case of erysipelas was moved as far away as possible He used carbolic acid and bichloride of mercury douches

FOREIGN CORRESPONDENCE

LETTER FROM PARIS

(FROM OUR OWN CORRESPONDENT)

Glaucoma—Iridectomy in Detachment of the Retina—Seltzer Water for Burns—Examination of the Urine in Diagnosis of Alcoholism—Chloral in Puerperal Eclampsia

In a critical review of Schnabel's work on "Glaucoma," Dr Fano, in the *Journal d'Oculistique*, remarks that the greater number of ophthalmologists continue to admit that every affection of the eye, in which the tension of the organ is augmented, is a

glaucomatous affection They persist in taking the *effect* for the *cause*, and they thus comprise under the generic name of glaucoma diseases essentially different one from the other They confound certain cases of irido-choroiditis with plastic suffusion in the vitreous body (true glaucoma), and certain forms of atrophy of the optic nerves accompanied by hypersecretion, or rather by a slackening of the work of the absorption of the intra-ocular liquids (false glaucoma) They arrive at compromising and discrediting an operation, that of iridectomy, so efficacious in true glaucoma, so powerless in false glaucoma The work published by Schnabel, Dr Fano states, is a refutation of the doctrine of glaucoma admitted by the greater number of ophthalmologists, to wit that the affection is caused by an occlusion of the filtrating passages of the irido corneal angle of the anterior chamber, on the grounds that there exist certain cases of glaucoma without this occlusion, and there are cases of occlusion without glaucoma On this theory was founded a most singular therapeutic remedy—the drainage of the eye Dr Fano approves of the proposition of the above-named author, viz that the cure of glaucoma by iridectomy is not due to the operation producing a filtrating cicatrix, which latter condition Dr Fano considers an anatomo-pathological heresy He also considers that glaucoma is not due to excavation of the optic papilla nor to an augmentation of the intra ocular tension, as, if there are a great number of cases in which may be found a particular excavation of the optic papilla accompanied by an augmentation of tension of the globe of the eye, there are other cases in which this excavation does not exist, although the eye be more distended, whilst in others again, there exists an excavation of the optic papilla, without the tension of the globe of the eye being augmented

While on ophthalmological subjects I may here note another important question treated by Dr Fano, viz the value of *iridectomy in the treatment of detachment of the retina* According to the author, whose opinion is entitled to some respect, this affection is not an idiopathic lesion It is the consequence of a choroiditis, as there are serous or sero-sanguinolent effusions in other parts of the body constituting œdemas and dropsies, so there may be in the sub-retinal region In the latter case, the effusions are the result of an obstacle in the venous circulation of the choroid To attack by divers operative procedures simple puncture, or puncture followed by irritating injections, drainage of the retinal sac, detachment of the retina, is to combat the effect, without suppressing the cause of the malady In performing iridectomy we effect a local bleeding, in the neighborhood of the diseased part Iridectomy, the author adds, is an antiphlogistic treatment directed against choroiditis, which treatment is founded on the ground of the anastomoses which exist between the blood-vessels of the iris and those of the choroid If this expedient should succeed in arresting the progress of the choroiditis, the sub-retinal effusion will be resorbed, if the inflammation of the choroid is not arrested in its progress, the effusion will subsist, or even increase

In a paper read before the Medical Society of Nantes, Dr Dubois, of Villers-Bretonneaux, stated that in several cases of extensive and superficial burns, he discovered a means of almost instantaneously arresting the pain arising therefrom This consists in slowly and continuously pouring over the affected part the contents of a syphon of Seltzer water In one case the doctor, by way of experiment, replaced the Seltzer water by a stream of cold pure water, but the pain, which had been subdued by the former, recommenced, and disappeared again when it was reapplied Dr Dubois explains this effect by the combined action of cold and of the carbonic acid He does not, however, ascribe to this remedy a curative effect, but maintains that the recovery may be accelerated by this application Moreover, besides its efficacy, this remedy recommends itself by its simplicity

At a recent meeting of the Société de Biologie of Paris, Dr A Robin read a paper illustrating the utility of the examination of the urine as a means of diagnosis in alcoholism He was directed to this subject by the history of the case of a patient (a lady) who was laboring under symptoms of alcoholism but, owing to her social position, the diagnosis was rather difficult to establish This, however, was effected after the examination of the urine, which revealed the following characters Excessive diminution of the solid materials (9 grams for 950), diminution of urea (0 790), and of the nitrate total (1 gram 072), augmentation of the relative proportion between the produced and the normal phosphoric acid All these characters constitute a syndrome which the author had met with in other alcoholic subjects On minute inquiry being made after examination of the urine, it was ascertained that this lady absorbed from 300 to 400 grams of alcohol per day

In the treatment of puerperal eclampsia, Dr Du jardin-Beaumetz prescribes chloral, from 8 to 12 grams per day It is administered by the rectum or by the stomach, but the preference is given to the latter, and he recommends that 1 gram of the drug should be given every hour until the desired effect be produced The author vaunts this remedy as being the most efficacious he has ever found in the treatment of this affection A B

BUDAPESTH

The University of Budapesth — The Hospitals — Hysteria from Forced Sexual Intercourse—Cottage Hospital—Professor Koranyi

This city, which is not difficult of approach from Vienna, is well worth a visit from medical men, who pass any time at all in Vienna The situation of the city is a fine one, on both sides of the Danube, being really two cities, under one government Buda or Ofen, on the south side of the river, and Pesth on the opposite shore Buda is on a hill and has the imperial residence, and from here magnificent views can be obtained of the river below and Pesth and the plains extending beyond The trip on the river be-

tween Budapesth and Lintz, some distance north, is one that will well compare with any sail in Europe The city, and, ordinarily is meant that part called Pesth, has some fine streets and buildings, notably Radial street, lined by handsome villas, and terminating in the park, horse cars and all the conveniences and luxuries necessitated by a thriving city of half a million inhabitants One of the buildings that most interested me, was that used as the headquarters for the distribution of the well known aperient water Hunyadi Janos

The University here, has about 3000 students connected with it about 1,100 belonging to the medical department, 1,500 with that for the law, and the remainder being connected with that for philosophy, philology and kindred branches

We visited three hospitals under the guidance of my friend Dr Hirschler, a native of the city All these hospitals had been built within five years, thus all having the very best and latest methods of ventilation, sanitation, heating and arrangement for work the first hospital, that for medical cases seemed almost perfect to me, who had just come from the ill adapted wards of Vienna, with their wooden floors and wooden beds and the like Here the wards were not large, the floors made of tiles, and the walls so constructed that they can be easily washed each bed, they are all simple and made of iron, have what seemed a very generous amount of cubic feet of air, allotted to it and the beds, each with its neat little table, were so arranged that much of the grim hospital look was lost Here was one of the very best cases of argyria ever seen, due to previous maltreatment

Perhaps the most interesting case, was one of hysteria in a young woman of 22, the effect following a forced sexual intercourse by her father She was a person of full average intelligence, but now more or less inclined to silence and gloominess There was complete anæsthesia in the entire left side of the body, skin, conjunctiva, mucous membranes, vagina and soles of the feet, with hyperæsthesia in the other half It was on this patient that I saw the most successful results of hypnotism I go into this case more or less fully, because of the impression made upon me, after the unsuccessful, or only partly successful results that I had hitherto seen, not then having seen the master, Charcôt Under the influence of Dr Hirschler, by simply concentrating her gaze upon a lead pencil, held before her eyes, she was put under the hypnotic conditions The sleep, in its beginning and continuance, seemed natural as may at any time be ordinarily observed When completely hypnotized, all the *muscles* were firmly contracted, and as the saying goes, "she was as stiff as a board " She could be held by the head and heels, in a perfectly straight and stiff position, with no support to her back, and her limbs, when forcibly placed in any position, no matter how strained or unnatural, would remain in that position When the arm was moved in any direction, the leg of the *same* side assumed a similar one, and the corresponding eye had nystagmus in more or less the same direction She had perfect control over every muscle, and movements of coordination were well performed at the instigation of Dr H He would simply say, "Now, Marie, *do*" this or that, and she would carry out what his words suggested, no matter how ridiculous or unnatural When told that there were hens in the room, she shook her skirt at them, when a dog was spoken of, she shrunk back, at the statement that her friends had come she stepped forward, smiled and extended her hand The gestures and emotions of surprise, *horror* and astonishment were all performed at the corresponding suggestions She answered questions that were asked her correctly, gently rubbing her throat caused her to sing, drawing the skin about the eyes into wrinkles brought out sad and mournful notes, and words that were translated to me from the Hungarian as those of one of their plaintive hymns, pulling up the corners of the mouth caused lively notes and gay words Finally, an interesting test was made Several pieces of blank paper, about the size of cabinet photographs, were handed to her, on one of which was a blot of ink She was told that they were photographs of different people she knew, and she was to pick out a certain doctor whose name was mentioned With her eyes still closed, she gazed at each one as she went through them, till she came to the *one specialized by* the blot, this she kept longer than the others, and started as if to give it as the desired one, she hesitated and put it under the others and continued through the pile, but soon went back till she had found this blotted paper, and after gazing at it, more or less intently, handed it to Dr H After this he simply blew upon her face and she awoke, exactly as if from a natural sleep As soon as she saw me, she began to cry, *not having seen me before she was hypnotized* For a while she acted as one more or less dazed after a heavy sleep

There is a fine laboratory connected with the hospital, with every convenience for chemical, pathological and bacteriological work Before leaving the hospital, I had the pleasure of making the morning visit with Professor Koranyi, chief of the clinic We then visited the children's hospital, one of the best appointed and finished hospitals one can find

Still further out from the city is the newest hospital, on the cottage plan, one building being given up to the homœopathic belief Among the other admirable arrangements were the bathing facilities, besides the ordinary ones, there were two large tanks for swimming purposes, so arranged that water of any desired temperature can be supplied Patients are ordered these swimming baths as part of their treatment

There are two obstetrical and gynecological clinics, one of 60 beds and one of 40 beds, where on the average there are 500 births and 200 gynecological operations a year

Any physician having the opportunity, will find a visit to Budapesth full of interest, and the medical profession, so far as I met them, very cordial and entertaining GEORGE W NASH

DOMESTIC CORRESPONDENCE

THE TOBACCO POISON

Dear Sir —The remarkable case of irascibility or mental disorder from tobacco, reported by Dr Batten, is not so exceptional as it seems, for I know a similar instance in which the fumes of tobacco irritated the brain and mind to such a degree that the afflicted gentleman is so forcibly impelled to assault the offending smoker as to require a very decided effort on his part to resist the impulse thereto Many a time he has prevented himself from doing so only by hastily turning and going away from the transgressor Indeed, for the time being, he feels like killing the smoking offender, a lamentable state of mind to be artificially induced by an extraneous toxic agent, especially one in such common use as tobacco Nothing else affects him so but tobacco, hence he is obliged to keep away from those who smoke altogether, which is a very difficult thing to do, as they intrude almost everywhere, smokers seeming to be under the false impression that they have a right to diffuse this powerful tobacco poison and afflict people at pleasure He is thus frequently in danger of involuntarily committing a crime for which he will not be responsible, as the disposition thereto is impulsive, otherwise he would never think of such a thing as an assault, much less murder, his soul revolting at the thought, being a respectable, temperate, peaceable citizen, with no disposition to do wrong or harm any one, using no stimulants, not even coffee, as it gives him neuralgia and increases his susceptibility to to bacco But worse still, this temporary excitement of mind from tobacco smoke is followed by prolonged mental depression with disposition to suicide, so that he has to keep out of the way of razors and other harmful articles, for fear that in some weak moment, he might use them to his own destruction This is a terrible life to lead, from no fault of his own either, but caused by the vicious action of other people in using and diffusing a poisonous nicotian agent, which is entirely preventible, by avoiding the smoking of tobacco altogether, or at least in public

From this, and other evidences to the same effect, which might be adduced, it is probable that the use, or exposure to the fumes of tobacco, is an occasional occult cause of quarrelling and fighting, or even murder, and a frequent source of dejection, hypochondria, melancholy, and suicide, so common, as well as nausea, vomiting, dyspepsia, biliousness, headache, neuralgia, neurasthenia, and other nervous, cerebral, and cardiac affections, malaise and systemic prostration, ill health of various kinds, with slow or sudden death, for there is no doubt that some, at least, of the many sudden, as well as lingering deaths, are from this nicotian poison, tobacco heart, depression and cachexia, or nicotism, like alcoholism, being very frequent These are only some of the fearful penalties that susceptible persons have to pay for the indulgence of smokers, who inflict this baneful tobacco poison upon them without regard to their health or right to be exempt from this with every other other noxious agent or injury, for which they should be severely punished, and the smoking of tobacco prohibited by law in all public places Tobacco smokers should be obliged to keep the poisonous smoke to themselves, as it is selfish, cruel and criminal to inflict it upon those who wish to be free from its pernicious influence Instead of the victim apologizing to the offending smoker for his artificially induced nicotian irritability or mental derangement, as in Dr Batten's patient, the apology is not only due from the smoker for poisoning him, but he is criminally liable for the offense, as he has no more right to compel him to inhale the collective nicotian principles in the form of smoke, than he has to force him to take the most active poisonous constituent—nicotia—separately, or to thrust solid, powdered, and liquified tobacco, or other poison, into his mouth and nostrils

The deleterious effects of tobacco upon the human organism are well known It is particularly obnoxious and penetrating in the form of vapor or smoke, especially to susceptible people, as there is a very large number of impressible, nervous, sensitive, enervated, feeble, ill and sickly persons—men, women and children—who are more or less seriously discommoded, sickened, and injured, or killed directly or indirectly, thereby, and no one has any more right to pollute the air with this pestiferous tobacco miasm or smoke than with chloroform or other poison, and compel people to breathe this potent malaria of tobacco, to the damage of health, mentality, morality, an often danger or destruction of life itself It is a very serious offense, indeed a grave crime, for any one, by means of this noxious nicotian miasm, as with any other baneful agent, to change or derange the mental and moral with the physical nature or disposition and entire being of others to their detriment, and make them vicious and criminal, infuriate, exciting to assault and murder, despondent and disposed to suicide, as well as diseased and shortlived, when otherwise they would be amiable and benevolent, exemplary and decorous, cheerful and happy, healthy and longlived

GEO J ZIEGLER, M D

Philadelphia, Oct 1, 1887

PREVENTIVE TREATMENT

Dear Sir —In THE JOURNAL of October 1, 1887, I notice a paper entitled "Aids in the Prevention of Fevers," by Dr R W Seay, of Louisiana It may be of some corroborative interest to readers of THE JOURNAL to have my experience in the same line laid before them Having a city practice and being particularly interested in midwifery, it has been my fortune, good or bad as the case may be, to be called upon to treat quite a large number of abortions, both natural and the result of criminal practices, either by the patient or some of the professional scoundrels that abound in all cities It has for four or five years been my practice (as an absolute rule), in all these cases, to give for the first 72 to 96 hours after the expulsion of fœtus, etc, hourly doses of tinct veratrum viride I have never given large doses, having found 1 gtt an hour for 16 hours

out of the 24 to be amply sufficient I have never had a single case in which any serious inflammatory trouble has arisen I was first led to this practice by reading what Professor Fordyce Barker has said of the use of veratrum viride in puerperal fever I believe I owe my perfect exemption from inflammatory results to this practice directly and specifically After all severe forceps deliveries and turning operations I do the same thing, and my obstetric record is clear thus far An ounce of prevention is better than a pound of cure, and nowhere is this more true than in guarding against possible ills following so important processes, so intimately connected with the preservation of our homes and the perpetuation of the race Childbearing is the noblest function, and motherhood the most beautiful and endearing condition of any true woman, and as physicians it is our duty to rob it of every possible danger so far as we can do so

JOHN W JOHNSON, M D (Harvd)

Boston, October 10, 1887

INTUBATION

Dear Sir —In the last issue of THE JOURNAL appears an article on the above subject in which the writer claims an improvement, and would extract the tube by threading the extractor into it (The thread being attached to the tube) An ordinary person would not go to that trouble but would simply pull on the thread It is not an improvement to leave the thread attached, but if left then the extractor would be entirely unnecessary

F E WAXHAM

3449 Indiana Ave , Chicago

NECROLOGY

WILLIAM WORKMAN, M D

William Workman, M D , was of Scotch English descent, born at Colerain, Mass , in 1789, and died at Worcester in his 88th year Fitted for College at Hopkinton Academy, under Rev Daniel Huntingdon, he began the study of medicine in 1822, in the office of Dr Seth Washburn, and in the fall of that year attended lectures at Harvard University, continuing his studies with Drs Flint and Mather till Aug 25, 1825, when he received the degree of M D from Harvard College He immediately commenced the practice of medicine at Shrewsbury, where he remained for ten years In 1828 he married Sarah Paine Hemenway, whom he survived about four years

In 1835 he went to Worcester and continued the practice of medicine till 1861, when he retired He became a member of Massachusetts Medical Society in 1831, was elected Councillor in 1840, which position he held till 1864 Was chairman of the committee of arrangements of its annual meeting at Worcester in 1851, and delivered the annual address at Fitchburg in 1852 Was a member of the American Medical Association, and attended as delegate in 1853, 1855, 1860, 1865, 1866 and 1868 In 1831 he joined the Worcester District Medical Society, was Secretary from 1840 to 1844, Censor from 1844 to 1849, Vice-President from 1844 to 1846 and President from 1846 to 1849, and before his death gave the society his medical library He was an earnest and constant student with quick perception and sound judgment, was a progressive and conscientious practitioner He was a public spirited man, giving liberally of his time and means to matters of public importance From 1840 to 1850 he served with Judge A B Foster and Rev Drs Sweetser and Hill, on the board of overseers of schools, and after Worcester was made a city, served on its public school committee He was one of the founders of the Worcester Co Horticultural Society, was trustee for many years, then Vice-President, declining the election of President

In 1862 he was appointed by Gov Andrew, a trustee of the Worcester Lunatic Hospital, and reappointed by Gov Bullock in 1867 In 1862, at the time of the seven days' battle, was telegraphed to in behalf of the sanitary commission, for volunteers to act with that organization in caring for the sick and wounded, although then 64 years of age, he at once offered his services, and went to Fortress Monroe, as surgeon, in charge of a Government transport He was a member of the Union church from 1840 to his death, and always maintained an upright and conscientious Christian character

After his retirement from active practice, he devoted his time to books, and kept well posted in the live issues of the day, the infirmities of age did not dull his perceptions or injure the vigor of his intellectual faculties The sufferings of his last illness he bore with Christian fortitude, knowing the end was near, and calmly awaited the time when the summons to depart should come

Four children survive him Sarah E , wife of John O Smith, of Chicago, Elizabeth W , widow of the late Dr H McPherson, of New Jersey, Louisa J Workman and Dr William Hunter Workman, of Worcester

M G P

BOOK REVIEWS.

A MANUAL OF TREATMENT BY MASSAGE AND METHODICAL MUSCLE EXERCISE By JOSEPH SCHREIBER, M D , member of K K Gesellschaft der Aerzte of Vienna, formerly Docent in the University of Vienna, etc Translated, with the Author's permission, by WALTER MENDELSON, M D , of New York 8vo pp viii—285 Philadelphia Lea Brothers & Co 1887 Chicago A C McClurg & Co

At the close of the first chapter of his book Schreiber draws the following conclusions from personal experience 1 Every physician having the inclination and ability, no matter where he may practice, may acquire, self-taught, and successfully employ the methods of mechano therapy in the treatment of disease 2 The absence of apparatus such as is generally found in the regular establishments is no insurmountable obstacle to success It

may only render the application of the system a little more difficult, and perhaps retard the cure somewhat 3 Old and special cases, requiring special means, special experience, and special treatment, are best referred to the establishment of some specialist 4 Laymen, by instruction, and by observing others, may be trained to perform all the various manipulations, but allowing them the independent treatment of a case is not always without danger to the patient

The second chapter of the book is devoted to a consideration of the physiological, primary, and secondary effects of mechanical interferences, and of the evolution of heat in muscles as a result of mechanical concussion In the third chapter the mechanical interferences used are fully described, and the fourth chapter may be said to be in part a continuation of the third, inasmuch as "active movements," "calisthenics and the Swedish movement-cure," and "apparatus" are described, together with the physiological effects of gymnastics on the heart and circulation, on the skin and kidneys, on corpulence, on respiration, digestion, the central nervous system, and on the mind The fifth and last chapter, of 175 pages, is on the *diseases suited to the application of mechano therapy* In it are considered "only such maladies whose successful treatment by mechanical means is beyond all doubt, and is generally recognized by the whole medical profession" These maladies the author divides into six groups 1 Mechano-therapy of neuralgias and muscular rheumatism 2 Sprains 3 Chlorosis, chronic catarrhal gastritis, pulmonary phthisis, hysteria, hypochondria, diabetes mellitus 4 Cerebral congestion, hæmorrhoids, and pulmonary emphysema 5 Chronic dyspepsia and constipation 6 Chorea and writer's cramp This chapter, as well as other portions of the work, is profusely illustrated

We have no doubt that this work will prove a most valuable aid to the proper understanding of a subject to which too little attention is paid But one or two works on the subject, of which we have any knowledge, are at all equal to it, and certainly none are superior to it The translation has been made by an accomplished German scholar

MISCELLANEOUS.

HEALTH IN MICHIGAN, SEPTEMBER, 1887 —For the month of September, 1887, compared with the preceding month, the reports indicate that bronchitis, typho malarial fever, influenza and typhoid fever increased, and that cholera infantum, cholera morbus, dysentery, diarrhœa, whooping cough, and remittent fever decreased in prevalence Compared with the preceding month, the temperature in the month of September, 1887, was lower, the absolute humidity was less, the relative humidity was more, the day ozone was much less, the night ozone was about the same Compared with the average for the month of September, in the nine years, 1879–1887, intermittent fever, remittent fever, consumption of lungs, cholera infantum, diphtheria and whooping cough were less prevalent in September

For the month of September, 1887, compared with the average of corresponding months, for the nine years, 1879–1887, the temperature was lower, the absolute humidity was slightly less, the relative humidity was more, and the day and the night ozone were less Including reports by regular observers and others, diphtheria was reported present in Michigan in the month of September, 1887, at fifty one places, scarlet fever at twenty one places, typhoid fever at forty six places, measles at five places, and small pox at one place

AMERICAN PUBLIC HEALTH ASSOCIATION, RAILWAY RATES —The Association will meet in Memphis, Tenn, on Tuesday, November 8, at 10 A M , and continue four days. The "Monon Line" (Louisville, New Albany and Chicago) and Chesapeake, Ohio and Southwestern Railroads have arranged to run a special Pullman sleeping car from Chicago to Memphis without change A number of delegates from Illinois, Michigan, Minnesota, Indiana and Iowa are expected to attend The railway fare for the round trip will be one and one third fare Dr Irving A Watson is Secretary of the Association and Dr G B Thornton Chairman of the Local Committee of Arrangements A number of exceedingly interesting topics will be discussed at the meeting The first meeting of the Executive Committee will be held Monday, November 7, at 4 30 P M The headquarters will be at the "Gayoso," on Shelby St

A PRIZE OF FIFTY DOLLARS IN GOLD is offered for the best essay on The Mutual Relations of Physician and Pharmacist The essay should endeavor to show how the ideal harmonious relations between physicians and pharmacists, both as individuals and as represented in their respective organizations, may be best realized, and all competitors must be governed by the following conditions

1 Any one interested in the subject may compete 2 The essay must not exceed 2,000 words in length and must reach us previous to January 1st, 1888 3 The MSS must be free from the author's name, address, or other marks of identification, and we recommend typewriter copy wherever practicable 4 The author's name and address must be enclosed with the manuscript on separate paper 5 All the essays submitted in competition for the prize are to be the property of the *Pharmaceutical Era*, and to be published or not at the discretion of the editor, but names of authors will be suppressed if requested 6 A committee consisting of five representative men chosen from the medical and pharmaceutical professions to whom the essays shall be submitted anonymously, shall award the prize, and the names of the committee will be announced with their decision

NINTH INTERNATIONAL MEDICAL CONGRESS

ADDRESS DELIVERED BEFORE THE SECTION FOR DERMATOLOGY AND SYPHILOGRAPHY

BY A R ROBINSON, M D, L R C P & S, EDIN
PRESIDENT OF THE SECTION

It devolves upon me as Chairman of the Section of Dermatology and Syphilography, to perform the very pleasant duty of offering, on behalf of my American colleagues, a most hearty welcome to our foreign co workers who honor us with their presence, and give us such fresh proofs of their deep interest in science by traveling so far to attend this meeting and to take an active and important part in the pro ceedings, although from our past history they must have very slight hope of any intellectual compensation from us And whilst we do not promise them as warm a reception from the authorities who regu late our weather conditions, as, according to rumor, the wind organs from certain quarters promised them weeks and months ago, yet they may rest assured that we are very glad indeed to see them present, and whilst we recognize them as leaders, as representative men in our special department, the men who have done and are still doing real scientific work, and in whom we place much hope for future advancement of our knowledge of subjects, still altogether too numerous in this branch of medicine, of which we know almost nothing, we would also gladly have welcomed a greater number of their col leagues, and regret the absence of several who, from illness or other causes, are unable to be present, although most anxious to have come

It is fortunate that the heat will not be so great as the false prophets promised, for, knowing the effects of high temperature upon the mental powers, and the amount of raiment one can wear under great heat conditions, and that these medical congress meetings are partly scientific and partly social in their character, it is evident that for a successful congress of this kind, the participants must be clothed and in their right minds If the social part is a comparative failure, I trust that the mental food offered will be rich in valuable material The American supply to past congress meetings has hitherto been an unknown quantity, for this meeting we already know the quantity, and will soon know the quality

You, as specialists, are too familiar with the dermatological literature of America, vast in yearly amount, meagre in contributions, not to wonder why, with so many writers upon the subject, with so many dermatologists animated with that peculiar American quality called "push," we have contributed so little to the recent substantial advancement in our knowledge of skin diseases But if we consider, as we now intend to do briefly, all the conditions under which we pursue our studies in this country, it will appear strange that good work is not even rarer than it now is

Taught in colleges, the majority of which require only a two years' course of study, the sessions of each year lasting only five or six months, what inducement do such colleges hold out to their students to study medicine as it should be studied, if they are ever to be other than the blindest followers in the pursuit of our profession of the advice received from a few lectures or compendiums? Such a college course was, perhaps, not objectionable in colonial days, or when physicians were not a drug upon the public, as they may be said to be now, when every village is overcrowded, and continual efforts to get patients are necessary to enable the professional man to build up a practice, and at the same time, financially, to make both ends meet It must be clear to the members of every teaching faculty in the land that a two or even a three years' course of study is quite inadequate to prepare a student—even if he be a student in the best sense of the term, bright and diligent—for the responsible duties of a medical practitioner, for the faculty is the examining body, and the superficial knowledge of candidates for graduation must be painfully evident to the professors

Lectures upon special subjects are given in the majority of the colleges, and in some of them dermatology is considered as a special subject, in which case, one clinical lecture a week is usually given As however, no examination upon the subject is required for graduation, the majority of students absent themselves from the lectures, but afterward receive their diploma, certifying to their knowledge of medicine in all its branches, although they may not have seen a single case of cutaneous disease, and could not diagnose an ordinary syphilide from an eczema, or even an elephantiasis from a scleroderma

Afterward in practice, however, they treat all patients with cutaneous diseases without hesitation, as

a rule, and with the utmost coolness and outward appearance of confidence in their knowledge of the "rash," for to them it is a rash and nothing more I am not blaming those general practitioners who follow this course, it is the legitimate result of the doctrine of the teaching body, for with only a two or three years' course it is not possible to devote time to subjects upon which they are not to be examined Neither do these remarks apply to those general practitioners of whom there is quite a number, who have devoted post-graduate time to the study of cutaneous diseases

But yearning after practical points—what drug to give for this or that disease, what is the best prescription for an eczema for instance—signs pathognomonic of imperfect mental training, and the lack of clinical experience, and of the information contained in good text books upon special subjects, bring about other evils which particularly concern us as dermatologists, and to which I will directly refer

On account of the few lectures given upon skin diseases, and the short course of study required, it is not possible to learn dermatology in this country, except under great disadvantages at least It is true that private instruction can be obtained at some dispensaries, and that regular clinics are held at some of the post-graduate schools, but for any extended knowledge of the subject a trip to Europe has hitherto been considered necessary Vienna has usually been the Mecca for those who wish to specially study this subject, as the magnificent material to be seen at the Hôpital St Louis has not drawn many students to Paris, whilst in London the patients are not used specially for teaching purposes, and consequently the advantages for studying the subject are not to be compared to those of Vienna

How long the student, now a physician, remains abroad depends usually upon his ideas of the proper course to pursue, and the amount of money at his command He should remain several years for the study of histology, pathology, morbid anatomy, internal medicine, bacteriology, and skin diseases, if he intends practicing afterwards as a specialist, but that is not the course usually pursued He devotes too much time to learning the diagnosis and treatment of skin diseases, a course very proper for a general practitioner, but not for one who ever hopes to advance our present knowledge of cutaneous diseases, for who can expect to add to the descriptions of clinical symptoms as given by such acute observers as Hebra, Wilson, Tilbury Fox, etc , observers who have devoted their lives to the subject, and seen their thousands and tens of thousands of cases I do not say that it is impossible to do so, but he has not a heavy heart or weak imagination who expects to make a reputation in that direction

To combine, as is frequently done, the subject of cutaneous with genito-urinary diseases, instead of with internal medicine, is a serious error, for the two classes of diseases are in no way related to each other, and a knowledge of the one does not aid us in the study of the other, whilst every one must admit the close etiological relationship of many cutaneous diseases with internal pathological conditions

Histology, normal and pathological, bacteriology, and general pathology hold the same relations to dermatology that they do to the other branches of medicine and surgery, that is, they are essential to the foundation of a broad view of the subject, and no one can fully discuss the etiology of the majority of diseases—that important branch of medical science which at the present time is studied more than any other—without some knowledge of them

Whether the student remains abroad for a few months only or for several years, he receives the foundation of his dermatological knowledge in foreign lands, be that slight and dangerous, or broad and capable of being built upon, according to the time and brain energy spent The majority of dermatologists at present practicing in America have obtained their schooling in dermatology in other countries, and as they continue afterward to be more or less influenced by the teaching received abroad, they may be called followers of this or that school, depending upon the country in which they studied

A school can exist only when there is a comparatively great dermatologist in a given country, one whose views are more or less unreservedly accepted, and his teachings followed by his countrymen, or when the leading dermatologists of a country hold similar and peculiar views As our knowledge of cutaneous diseases increases, and the number of dermatologists multiplies there is more and more difficulty in founding a school, so that at the present time we are scarcely justified in speaking of a German, French or English school, for in all these countries eminent dermatologists, of whom there are always several in each country, hold very widely different views concerning the etiology, nature and treatment of the inflammatory affections of the skin, and it is upon the divergence of views in reference to this class of diseases particularly, that schools have existed

As there is no particular centre for dermatological study in America, as there is no comparatively great dermatologist, and finally, as the majority of dermatologists have had their schooling abroad and hold widely different views on the inflammatory and other cutaneous diseases, there is no such a thing as an American school of dermatology, consequently, also, there cannot be a representative American dermatologist, for there are no special American views of dermatology to be represented

This is specially gratifying to your Chairman, for, that being true, it logically follows that it cannot be said of him for the present occasion that he is not a good representative of American dermatology As independent workers each of us represents but the character of our own labors, and if that is not creditable, the author is a corresponding dermatologist If the work done by American dermatologists, as a whole, is to be represented, then the position should not be a difficult one to fill, for the average of that work is not astonishingly high, as shown by the articles in journals, and the reports of our special societies

Returning from his European travels—"speaking a foreign language just as well as his mother tongue"—the would be specialist is beset by temptations to which he too frequently falls a victim With more medical journals in the land than are necessary for the publication of papers that repay one for their perusal, there is, on the one hand, a demand for an article on some subject—it matters not what it be—by the editor, and, on the other hand, a desire to publish a paper by the specialist anxious for reputation and notoriety The medical world at least must know that he is devoting special attention to a particular branch of medical science, and what plan so good as to write an article for a journal and, by means of reprints scattered broadcast, let the world know your specialty, name, and address A few repetitions of this procedure will, without fail, bring patients to the office, and reputation among the mass of general practitioners Why this latter is a result is not difficult to understand As already mentioned, the college graduates usually have no knowledge of the so called special branches, consequently any reprint—although it be only a compilation of previous articles by real workers—and very often they are even very poor compilations—appear to the busy practitioner to contain valuable information, and the author thereof as one having special knowledge of his subject

This mode of action is a very serious evil, and must and does bring discredit upon the specialists in that branch as a body It is to be hoped that the protest I now enter against this evil will not be in vain, and that in the future only such articles will be published as represent real contributions to the existing knowledge of the subject discussed We still have so little real knowledge of diseases of the skin that there is a wide field for future observation, and the energy wasted in the compilation of these papers should be devoted to original and more creditable work Let us show that American dermatologists have the spirit and ability to do their share of work for the advancement of our knowledge in their special branch of medical science I do not wish to be considered as maintaining in this address that no good work has ever been done in this country, for that would not be correct—but it has borne no proper proportion to the number of articles which have been published, for too often the heading of a paper as a "contribution" to our existing knowledge of this or that disease has scarcely been justified by the contents

As we learn most from a contemplation of our errors, I have endeavored to draw attention, as regards dermatology in America, to the faults of the colleges with reference to this branch, and the errors of action which we as specialists are liable to commit for our personal advancement, and have pointed out the way by which creditable reputation, if not pecuniary success, can always be attained

Finally, in view of past events, I desire to express the hope that another International Medical Congress will not be held in America until the profession in this country have shown, by their actions, a change of heart, that they are prepared to subject the desire for personal gain to the proper, nobler and more honorable feeling for the advancement of medical science and consequent relief of human suffering

CLIMATE AND HEALTH RESORTS OF CALIFORNIA

Read in the Section on State Medicine, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY J W ROBERTSON, A B, M D,
ASSISTANT PHYSICIAN AND PATHOLOGIST NAPA (CAL.) INSANE ASYLUM

California has but recently attracted the attention of sanitarians This tardy recognition was partly due to its isolation, partly to the fact that the Argonauts looked not at the sky, but at the earth and cared nothing for scenery, climate or a pure atmosphere The Coast belt contained no gold, therefore they ignored it Southern California, where now bloom perennial orange groves and the rarest exotics, they pronounced a desert scarcely able to support a meagre growth of sage brush and cactus, a fit habitation for the coyote and the squalid Troglodyte Only recently has the fact been borne in mind that something is to be found more precious than gold, and from all over the world thousands of invalids flock here, they do not realize that California has a cosmopolitan climate adapted to all diseases that can possibly be benefited by change of air, that within its borders are to be found the altitude of the Alps, the scenery of Switzerland, the fruits of the tropics, numerous mineral springs which equal in value and are more healthfully situated than are those of the Eastern United States or Europe, the pure air of the Colorado Highlands and the winter climate of Florida, and that it is a nice question to always properly decide on that location best situated to relieve their particular disease They do not always choose wisely

Nor is this possible Every town, every mineral spring, every sea side resort, so loudly and so persistently bids for their countenance and so little reliable information outside of interested statements can be obtained, that they cannot intelligently select

I shall attempt to briefly outline the essential features of our climate, to explain in what particular respects we claim pre eminence for it, the rational of its therapeutic influence, and to mention those localities which are best adapted to certain classes of disease

While the climate of California is mainly due to its situation midway the temperate zone, the remarkable uniformity of temperature is due to local causes The great law that, in the Northern Hemisphere, all western coasts are warmer than the eastern, which is particularly well pronounced when the eastern is compared with the Western Coast of the United States The mean isotherm of 50° which passes through New York, latitude 41° bears north-

ward as it crosses the continent, touching the Pacific at Vancouvers Island, latitude 49° Nature also draws isotherms in her distribution of trees and plants While, on the Eastern Coast, 60° is the northern limit of Coniferæ they are found as high as 68° and 70° in regions adjoining the Pacific It is then evident that the climate of California is much more temperate than that of the Eastern States, which are situated in the same latitude; but this does not hold true of Southern California Here the conditions are reversed, San Diego, in the same latitude as Charleston, is 8° cooler San Francisco and Washington, in the same latitude and having the same mean annual temperature, have climates very dissimilar, owing to the great difference between the mean summer and winter temperatures of Washington, which amounts to 40°, and the small difference in San Francisco being not over 12° The mean annual temperature of Santa Barbara is 60°, San Francisco 55°, nor does it fall below this on the Northern Coast In Crescent City, 300 miles north, the temperature is as mild as is that of San Francisco, frost and snow being of rare occurrence

That this Coast Line, stretching through 8° of latitude, should have such remarkable uniformity of temperature, while phenomenal, is explained by the constant west wind which comes from the warm Japan current These winds bear with them the uniformity of temperature of large masses of water and render the West Coast climate warm in winter and cool in summer For this reason isothermal lines are, as they near the Coast, so deflected as to run North and South, and to mark out three climatic belts which I have named Coast, Valley and Mountain This division has been generally adopted and from a therapeutic stand-point answers admirably

The Coast climate extends several hundred miles North and South, and reaches from five to twenty miles inland

The Valley belt, beyond the Coast range, commencing with Shasta valley on the North, extends down through the Sacramento and San Joaquin Valleys into the arid plains of the Mojave and Colorado deserts, while the Mountain includes the Sierra Nevada beyond Rainless summers characterize all these regions

That portion of California which has obtained the greatest reputation, which has filled the eyes of strangers with visions of a land where the orange and the vine flourish, where the tenderest plants grow unprotected, where it is neither so warm as to be sultry or so cold as to necessitate fire, where nature has so blended her charms as to hush the murmurings of the most fastidious invalid, is along the Coast and the adjacent country directly influenced by it And this is of truth a wonderful region A Coast line extending through 8° of latitude where snow is phenomenal and frost rare, where the mean daily, monthly, and annual temperature varies within a few degrees only, where the bright sunshiny days are the rule and sultry ones unknown, where the fresh salt air so invigorates as to prove an exhilerating tonic, and where flagging energies and a toneless system are revivified and thrown into a state of the highest tension, commands recognition To every picture there is, and should be, some dark lines In our enthusiasm we often forget to mention the fogs which float in from the ocean and enwrap us with a chilly embrace, that the breeze which so intoxicates us and which, by long habit, we have learned to call bracing, searches the marrow-bones of the unacclimatized and sends cold chills through the enfeebled frame of the invalid This holds true of that region only which is north of Point Conception and is directly on the ocean

Our boasted climate is only exemplified to the full in those places so far away from the Coast that the radiant heat will remove all rawness from the sea-breeze, or in those Valleys adjacent to the Coast but protected by the foot hills

The Japan current which hugs the Northern shores so closely, giving us a cool and bracing climate, does not exert the same influence south of Point Conception This is partly due to its waters being heated by the more southern seas and a hotter latitude, partly to the fact that it is at this point separated from the main-land and pushed to the westward by a warmer current The wind blowing over this no longer chills, but still exerts a decided influence For this reason certain portions of Southern California possess a climate in its way unapproachable and not to be rivalled the whole world over

So loudly, so ably and with such justice have its praises been heralded that to add were useless Even here, it is well, in selecting, that some care should be exercised Climatically speaking, the therapeutic area of Southern California is small It is limited to those localities only which are directly influenced by the ocean breeze and extends but a few miles inland In the Valleys back from the Coast, the summer heat becomes unbearable, there is but slight vegetation and good water is not easily procured The winters, however, are said to be mild, dry and wonderfully invigorating Only a few inches of rain falls and out door life is practicable

It is this region that first attracted the attention of sanitarians and gave California its greatest climatic reputation Even now the majority of invalids look to Los Angeles as to a new Mecca, and with ever increasing wonder behold the mighty changes wrought by the hand of man, which for once have far outrivaled nature even in her most lavish mood This climate speaks so strongly for itself, it is so mild and delightful that the most carping cannot find fault and the invalid susceptible to the slightest chill, utters no complaint For this reason it is taken for granted that it of necessity agrees What is agreeable does not always agree The climate of San Francisco, directly influenced by the cold ocean breeze, is not agreeable and makes but a poor impression on the visitor Beyond all other spots along the Coast it is disagreeable, and all drawbacks to the Coast climate are here illustrated in extreme This is caused by its location The Sacramento and San Joaquin valleys here have their outlet During the summer both are intensely hot and the rarified air, rising rapidly, forms a vacuum which the ocean breeze rushes in to fill The

Golden Gate is indeed a gateway, presenting no obstruction, and the wind sweeps through it, across the bay and up the Sacramento and San Joaquin rivers with great velocity During the early morning, and ordinarily, until near noon, the bright sky, the mild and bracing atmosphere makes one so tingle and scintillate with life that every nerve of the body and all the faculties of the mind are in a state of tension, and no more delightful form of intoxication can be imagined When the interior valleys, warming up, begin to suck in the cool sea breeze the gentle motion of the air adds a new delight In the course of an hour, all is changed It is no longer a breeze—it is a hurricane bearing everything before it that is ordinarily moved by such a force Between the town and the ocean stretch several miles of sand hills, and, fed by these, the streets soon become a swaying cloud of dust, fine sand and rubbish On gala days when the sun shines on the interior valleys with unusual intensity, small gravel is added, that cuts like a whip and fills eyes, nostrils and mouth with a grimy coat Strange to say the inhabitants soon become accustomed to this, and after a few months residence, this one drawback counts for naught against its more powerful claims for their approbation Along the whole Coast the heat of the interior causes a like afternoon breeze, but except in a few localities where a break in the foot hills gives it free sweep, is not disagreeable

This climate is susceptible of subdivision, the one just described being directly on the Coast, the other, more moderate, but of the same type, a few miles inland and protected by the foot-hills from the full force of the breeze Here lie many valleys with a climate equaling that of Southern California. Those which have become best known because of their proximity to San Francisco are the Livermore, Santa Clara, Napa and Santa Rosa Valleys None of them are distant an hour's ride but because of their location, the afternoon breeze is shorn of all harshness These are fast being occupied as summer resorts The country is rolling, well watered and fertile, bearing grapes, fruits and flowers in great profusion In summer the thermometer may register 70° or 80° at mid day, but such heat is exceptional The mornings and afternoons are never sultry, and the nights are cool Nor is there any evening fog During the winter frost occurs but rarely, and snow and ice are unknown

Still further inland, in the very heart of the foothills, there is a region which should attract sanitarians by reason of its promise of therapeutic usefulness It combines magnificent scenery, moderate elevation, and a bracing atmosphere with what promises to be most important mineral springs These occur in great numbers and in a country which, without them, would leave but little to be desired Fish and game abound and prove a sufficient attraction to force energy and life into the most lethargic and induce that amount of exercise necessary to vigorous health Volcanic products are here found in great abundance and mineral deposits are frequent Water, trickling through these, become impregnated with various salts, and, emerging as springs, undoubtedly possess some healing power Little scientific attention has been bestowed upon them, and, while a few have been authoritatively analyzed and honest efforts have been made to have them stand on their own merit, many have been given names and analyses, tending rather to prove their resemblance to some celebrated Eastern or European Spa, than to make plain the many and strong claims peculiar to themselves

While Sulphur, Vichy and Congress Springs may be rightly named, and their claims of resemblance to their more celebrated sponsors may be just, yet, because of their origin, it is no more probable that any two would resemble than that two kaleidoscopic pictures, although formed by the same glasses, should be identical The more disagreeable the water tastes, the more redolent it is of sulphur or the more stained with iron, so much the more eagerly is it sought after No matter what salts be contained in the water or what be their degree of concentration, the amount consumed is, as a rule, limited only by the capacity of the stomach or its ability to retain Thus abused their very best therapeutical effects cannot be obtained At a few of the more prominent resorts physicians are located who can give intelligent directions with regard to the waters and recommend or forbid their use, but therapeutical precautions are often disregarded

These springs are scattered over the whole State Provided they be easily accessible and the surrounding country, climate and scenery be such as to warrant the outlay a health resort is established, otherwise they are ignored Hundreds are found throughout the mountains of the Coast range in spots wild and inaccessible, but even these are by no means neglected Wild animals, either attracted by the singularity of the taste of the water or for proved qualities, flock to them, and their location is usually marked by numberless trails centering there

Various classifications of these springs have been attempted, but their ingredients so vary that no rigidly scientific system can be adopted Nor have the necessary analyses been made to even classify in accordance with the nomenclature ordinarily employed But crudely as they have been used and greatly as they have been abused, there is much and unanimous testimony as to their beneficial effects in certain chronic diseases Comparatively few springs are found either in the Northern or Southern parts of the State with more than a local reputation It is in Central California, in the foot hills already mentioned, that they abound Lake county, so named for the beautiful sheets of water within its boundaries, contains the majority of these, although many are found in the adjacent counties of Napa, Solano, and Mendocino In this region alone some thirty locations have been made, buildings erected and health resorts established At many of these there are several springs both hot and cold, the former being used tropically or in the form of bath, the latter internally

Clear Lake, surrounded by mountains, lies in the heart of this region It is easily reached from San

Francisco either by Calistoga or Cloverdale Daily stages here connect with the various health resorts, the time occupied in reaching the most remote not being over twelve hours from San Francisco

In the accompanying map I have figured those health resorts only which have an established reputation and where special preparations have been made to accommodate guests I find it impossible to accurately locate all the mineral springs There are very many in Southern California, especially in the counties of San Louis Obispo and San Diego which have only recently been improved Not having visited all these springs, and descriptions with reference to locality being vague, I can only approximate the situation of certain ones

The climate of the Valley belt I cannot unreservedly praise During the summer the thermometer ranges high, in certain localities registering 110° or over This heat is better borne than would be that of a like intensity in the East, because of the extreme dryness of the atmosphere This, like a sponge, absorbs moisture from the body with such rapidity as to cool the surface Probably this evaporation is so great as to dry the fluids in the body, and certainly act injuriously upon the mucous membranes of the nose and bronchial tubes Many cases of malaria, diphtheria and other endemic diseases here rankly flourish, partly due to artificial irrigation, but more especially found in those localities along the Sacramento and San Joaquin rivers which are annually overflowed During the winter months therapeutic benefit can be obtained even here by reason of the mildness of those localities far to the South or where the Coast range breaks and allows the warmer Coast climate to exert a moderating influence

Oroville, situated on the Western slope of the Sierras, is now regarded as the heart of the Northern citrus region, and the country adjacent is being fast settled by invalids who here combine a mild climate, with work not unpleasant

The winter mildness of the Sacramento valley is not altogether due to the warmer coast wind It lies at the foot and on the western slope of the Sierra Nevada mountains, which effectually protect it from the cold polar trade wind This is well illustrated by comparing the winter climates of the western and eastern slopes Truckee, on the eastern slope, is not uncommonly buried in ten to twenty feet of snow while Colfax and Auburn, just across the divide, are surrounded with green fields, and a little further down, fruit orchards and orange groves flourish

Lieut Maxfield, Signal Service Officer in charge of the station at San Francisco, has, at my request, compiled the table appended

The stations named are taken as types, being selected as most nearly representing the various climates The second column indicates the highest, while the third gives the lowest degree of heat registered by the thermometer during the whole month The other columns are sufficiently explained by their headings The stations located at San Francisco and Mendocino typify the climate of the coast belt Mendocino, projecting far into the ocean, is unduly

§ Form not received for this month

Red Bluff, Nov '85	52 7	71 0	38 5	58 5	46 7	11 8	23 5	4 0
" " Dec '85	49 3	68 0	33 0	55 3	43 6	11 7	21 0	5 5

exposed to the cold fogs and, for this reason, averages somewhat cooler than does San Francisco Both north and south of Cape Mendocino the climate closely approximates that of San Francisco Red Bluff and Sacramento fairly represent the climate of the valley belt Red Bluff, situated far north, is not so cooled by the sea breeze as is Sacramento

A comparison of the temperatures of Los Angeles and San Diego is apparently in favor of the latter city, which is a trifle cooler in summer and warmer in winter San Diego is directly on the ocean and is more exposed to winds than Los Angeles, for which reason many prefer the inland city

Unfortunately, there is no official report of the temperature of Shasta and Scott valleys, which occupy the extreme north of the valley belt, or of the eastern slope of the Sierras These are the only portions of California whose climate resembles that of the Eastern States There are four well-marked seasons The thermometer rises to 100° during the hottest days of summer and falls to zero or below during the winter This is due to the fact that Shasta and Scott valleys are separated from the coast by the Siskiyou Mountains, a range whose lowest pass is 5,000 feet above the level of the sea This effectually protects them from the modifying influence of the coast wind

Therapeutics —The difference between the subdivisions of the coast climate, viz that found directly along the coast and that of Southern California and inland valleys, is the difference between a plunge bath in the ocean and a tepid sitz bath which is so near the temperature of the body as to produce a feeling of languor only, in other words, should the patient be so feeble that the cold wind and salt air chill, and should the after effect be such as to leave him depressed and unrevived, a residence on the sea coast is not desirable, on the other hand, should the patient be more robust and of a naturally vigorous constitution, the cold air, at first chilly and raw, soon produces a state of well being Vigor and tone are infused through the body, difficult for one who has never experienced it to understand

But there are certain diseases, no matter what the constitution of the patient be, which are deleteriously affected by the coast climate Those suffering from rheumatism should especially avoid the coast and seek a residence either in the mountains or at certain mineral springs Shovel Creek Springs, situated on the Klamath river in the northern part of Shasta valley, has obtained a reputation for its efficacy in the cure of this disease Mud impregnated with hot mineral waters is used topically, and often succeeds in relieving those obstinate forms of chronic rheumatism when ordinary remedies fail Hot baths are also to be obtained, but are not to be recommended unless competent medical advice has been sought and the circulatory system found perfect Other springs noted for their efficacy in this disease are found in the lake country Much benefit has followed the internal use of the waters of the Bartlett and Witter Springs Fulton Wells and Paso Robles have also obtained a wide reputation Chronic bronchial and laryngeal affections are unfavorably affected by the raw sea air For these the foot hills, where the temperature is even and the climate mild, is a most suitable location

The Highland Springs of Lake County, both by reason of their climatic surroundings and the specific influence claimed for its waters, has been highly recommended

Those of a bilious temperament should avoid the coast For some reason, to me unknown, it acts injuriously upon such cases Avoiding the diseases just mentioned those otherwise affected may seek the coast with a certainty of benefit, provided that their constitutions be sufficiently robust to react in the bracing atmosphere Malaria never originates on the coast, and when contracted elsewhere and brought here, if mild, is at once cured, when more deeply rooted it assumes a remittent type and will often recover without aid of medicine Those cases of malarial poisoning accompanied by serious visceral lesions, which are of such frequent occurrence in the Southern and Southwestern States, and which medicine cannot relieve, should be sent to this climate Those kidney diseases which water impregnated with lime is supposed to aggravate are relieved by the use of the waters here, which, as a rule, are deficient in this

Certain waters strongly impregnated with alkaline carbonates, such as those found at Byron, Tolenas and Skaggs Hot Springs, are also very efficient in relieving these cases

Consumption is supposed to be favorably influenced by the modified coast climate It is true that the great majority of those coming to Southern California are of this class, but whether they derive any benefit outside of the hopes engendered and the exercise they undergo in their flight from death, I cannot say Provided that the etiology of this disease be settled, that the bacillus which is beyond question found in the tuberculous deposits be not an effect, but the cause, and that its multiplication results in lung destruction, then I cannot understand how any climate can materially benefit A germicide and not a climate is essential for a cure On the other hand, if it be an inherited disease, depending on a depraved constitution which at the least exposure is liable to break down and manifest itself by the formation of tubercles, then what improves and renders the body vigorous must also beneficially affect the lungs

Consumptives should be warned not to drink the water of or to bathe in the hot mud of the various mineral springs When the disease is advanced they should be kept at home, no matter what part of the world it be in

Many come to California in the last stages and only reach it to die among strangers When the advice of the physician is overruled and they must choose some climate, that region south of Santa Barbara should be selected, both because of its easy accessibility and by reason of its mildness and the unchangeable climate there found In the early period much can be hoped for from this climate Numerous health resorts have been established both directly on the coast and in the interior valleys For those incipient consumptives who are fond of sport and for whom an outdoor life is desirable, certain portions of the mountain belt are to be recommended Above 3,000 feet the oppressive heat disappears, though still warm, outdoor exercise can be taken without inconvenience Camp life can be indulged freely, the dry summers assuring freedom from inclement weather It combines together with magnificent scenery, a desirable elevation, dryness, a moderate temperature, and a pure atmosphere impregnated with the balsamic emanations of the pine and fir trees There is an immunity from all endemic diseases except mountain fever—described by Dr Kober in the last Report of the Secretary of the State Board of Health

This exposure to a dry and high atmosphere presents a hopeful prospect of recovery Nature here acts on the lungs in a manner similar to that of the pneumatic cabinet recently so much in vogue It causes the lungs to expand more freely and in this way assists in their development What specific curative properties altitude possesses over consumption I do not know I cannot believe that it is the mere fact of causing lung expansion Certainly less oxygen is obtained in an equal number of respirations As recent observations tend to show that germs do not readily develop in higher altitudes, this would be a plausible explanation Consumptives should be absolutely forbidden to use the mineral springs, as under no circumstances can benefit be derived Certain cases uncomplicated by bronchial lesion seem to do well on the coast This is probably due to lack of germs, for along the whole coast, except in the region of large cities, endemic and epidemic diseases are unknown The wind undoubtedly acts as a germicide

In a paper necessarily so brief, I cannot more fully enter into a discussion of the therapeutical effect of our climate I trust that in making this summary of the topography of California, its climate, its peculiar environment and its many natural advantages, I have made the subject so well understood that it will be possible for every thinking physician to draw the legitimate conclusions, and to so intelligently advise those invalids desiring a residence here, that they may select a proper location They should remember that much depends not only upon the disease itself, but also upon the condition of the patient and the peculiarities of his constitution

DISCUSSION

DR J M ALLEN, of Liberty, Mo The article just read is certainly very suggestive of prospective changes in our ideas of pathology The tubercle has been a puzzle to our profession for years It is but recently that the mass of the profession has accepted the idea that it was of inflammatory origin While it is not necessary for us to change from this position it seems more than probable that we will have to change our ideas as to the cause of this variety of inflammation, which we have ascribed heretofore to atmospheric conditions of heat, cold, moisture, etc , and add a new factor, the bacillus tuberculosis, which recent investigations have shown to be always present This throws new light on climatology Practical observation has long since taught us that locality, or the environment surrounding the human family, has much to do in determining the character of diseases they suffer from The absence of a disease from a certain locality carries with it the fact of the absence of the specific cause of this disease If this specific cause be a germ, it has a life to be supported by its environment, and can exist only when and where these essentials for its life and propagation exist Now the facts as stated by the author of this paper, that phthisis pulmonalis rarely occurs in certain districts in California, and when cases in their earlier stages are brought there they rapidly improve This carries with it the idea that the essential for the support and propagation of the bacillus tuberculosis are absent This idea is strengthened, I think, by the fact that our system of railroads and other means of communication are so perfect and rapid that the bacillus has undoubtedly been planted there, yet it has not lived and propagated for the want of the element necessary for the support of its life Further, it is a well established fact that there are localities in the West where fresh beef may be hung out in the open air for weeks (without salt) and no putrefaction occur This can only be explained by assuming that the bacteria of putrefaction are absent, or rather that the element necessary to support the life of this form of germ is absent Why may not the same be true in regard to the bacillus tuberculosis? Again, Dr Robertson in-

forms us that in some of the districts of California malaria has no local existence, and only exists when imported, after which it manifests itself in a very mixed form and finally ceased to exist, or becomes attenuated We all know that this is one of the most vigorous germs we have to deal with, and always exists wherever the elements for the support of its life exist In regard to phthisis pulmonalis it is a well established fact that irritation followed by inflammation does not necessarily produce tubercle But when the new factor of life is added, the bacillus tuberculosis, tubercle is always the result But not desiring to go too far in this direction, we will say that wherever there exists tubercle, the bacillus is present, then what part does it play in the production of this pathological process? It cannot be that of an irritant only, for we all know that irritation and inflammation alone cannot produce tubercle In view of the fact that this bacillus is a living germ that derives its support of life from its environment May it not be that it consumes for the support of its life certain cell-elements, the absence of which causes the cell to undergo the retrograde metamorphosis of tubercular formation? We hope that the author of the paper will bring us annually a report on this interesting and important subject, and that he will avail himself of any opportunity to press his investigations in the fresh and fruitful field of scientific research

DR A N BELL, of New York, stated that the promotion of phthisis may be found in dirty soil-moisture The smallest percentage of phthisis is among people subject to ocean atmosphere (by which is not meant a *coast* atmosphere) The dry atmosphere, whether in a high latitude or in a hot school room will draw moisture wherever it can get it and will draw it from the nares and bronchial tubes Englishmen go to Madeira, and others go to Nassau and Bermuda Some think they cannot live unless they go to these places every winter, and is so not because they are in a moist atmosphere but a *clear* one, and one that is unirritating It should be borne in mind that only about one-fourth of the cases of phthisis are hereditary, and that on most of our seacoast we have dirty soil-moisture—the soil impregnated with both animal and vegetable decomposition

DR J F HIBBERD, of Richmond, Indiana, said that while he had great pleasure in the paper, it was open to the criticism of not being sufficiently definite to enable a physician to select the particular location in California where he could send a patient with any given form or stage of consumption We needed more definite information It was possible that certain surroundings in any climate might determine whether a patient with incipient consumption should succumb to the disease or recuperate and be of sound health Dr Lynch, in his address before the Association this morning, told of an experiment recently reported in Baltimore, wherein fifteen rabbits of equal development were utilized Five of them were injected with bacilli, put into a dark, damp cellar, and all died of tuberculosis Five were likewise injected with bacilli, sent into the country, where they had good air and food and opportunity for appropriate exercise, and they all recovered Five were not injected with bacilli but were placed in a dark, damp cellar, and all died, but not with tuberculosis And to the same point was the testimony of Brown-Séquard with whom he (Dr Hibberd) had talked some years previously in Paris He stated that the rabbits and other animals used in vivisections had been placed in unventilated quarters, and nearly all died of tuberculosis, but when they adopted the plan of sending these mutilated animals to the country with plenty of good food, fresh air and exercise, they nearly all got well, though now and then one died of some traumatic accident

DR W L SCHENK, of Osage City, Kansas The careful observer notes the effects of various climates and localities upon health The scientific sanitarian should account for such results The author of the paper has told us that certain places in California are free from malarial diseases, while in other localities it exists abundantly My friend says "bacteria malaria," Another might say, simply "malaria"—an entity or nonenity that the most careful and scientific researches in chemistry or microscopy have failed to demonstrate In all localities where periodic diseases prevail with any considerable intensity, three factors exist, alternating heat and cold associated with moisture, the moist heat of the day enervating, the damp cold of night emptying the superficial capillaries until internal engagement involves periodic disease Moist heat enervates more than dry heat Moist cold chills more than dry cold Where there is alternating heat and cold with moisture there will be found malaria

DR HENRY B BAKER, of Lansing, Michigan, asked attention to the fact that three speakers, including the author of the paper, had coincided in mentioning localities and climates as favorable to freedom from malaria and to recovery from phthisis, the prominent character of which was small daily range of temperature, that is, slight difference between the day and night temperature This is true of California and the ocean climates On the other hand, in the inland States the malarial region is the region where there is great difference between the day and the night temperature And going from the North toward the South the malaria increases somewhat in proportion as the difference between the day and the night temperature increases

DR WOODS HUTCHINSON, of Des Moines, Iowa There seems to me no inconsistency between either Dr Bell's or Dr Hibberd's statements and the germ theory of the origin of phthisis The "dirty moist air" of the former is the chosen home and necessary environment of bacteria, while the "ocean air" is above all others essentially free from germs, inasmuch as they are too solid bodies to be carried over long ocean distances California atmosphere ought to be germless on account of the ocean on the West, and the desert and frozen mountain chain on the East, and this undoubtedly is one of the factors in its value for the treatment of phthisis The leading factor, however, in the efficacy of climate upon disease germs lies in the fact that it encourages outdoor exercise and improves the physique in every way

This is the one property in which the Engadine, Cuba, Los Angeles, and Madeira have in common The most effective germicide is a vigorous healthy organism Life is the deadliest enemy of disease and decay, and what we are endeavoring to accomplish with our cod liver oil and hypophosphites, is done much more effectually by mild, invigorating climates The vitality of the body is raised to where it can destroy any disease germ, whether tubercular or malarial

GERANIUM MACULATUM

Read in the Section on Medicine, Materia Medica and Therapeutics, at the Thirty Eighth Annual Meeting of the American Medical Association, June 7, 1887

BY JOHN V SHOEMAKER, M D ,
OF PHILADELPHIA

If the craze for therapeutical novelties could be diverted from the jungles of India and the laboratories of the manufacturing chemist, to the fields and forests of the United States, suffering humanity would be the gainer Many of the most highly lauded, marvelous synthetical products and wonderful drugs precipitated upon the profession during the past few years are not only useless but positively injurious, while scarcely 2 per cent of the remainder possess any practical value

Geranium Maculatum, to which I desire to redirect your attention to day, is not a new remedy imported over thousands of miles of land and sea at prodigious expense, neither is it the patented compound of forty stills, recommended as a sure cure for all diseases by forty medical theorists who do not know the difference between the pulse in health and disease, but it is one of the most valuable and yet the least known of American indigenous remedies More than 60 years ago Dr Barton, in briefly reviewing its medicinal properties, declared it to be certainly entitled to the attention of every American physician Yet notwithstanding the commendation of Dr Barton, and other distinguished observers, Geranium Maculatum has been almost entirely discarded Indeed, so seldom is it prescribed that druggists in many places do not keep it in stock When I began to investigate its merits five years ago, not one of the eight druggists to whom I sent for it had any on hand, and I was finally compelled to send to a wholesale house for the quantity needed

Geranium Maculatum contains tannic and gallic acids, gum, starch, sugar, coloring matter and various resin and oleo resins, which have not yet been studied Its value depends in large part upon the tannic and gallic acid present, but its resins, oleo resins and other constituents enhance its usefulness, and render it more potent in many affections than any preparation of tannic or gallic acid alone or combined The portion of the plant used in medicine is the rhizome, or the root stripped of its bark The dose of the powdered root ranges from 10 to 40 grains As it is soluble in water or alcohol it may also be administered in the form of the tincture or the fluid extract The dose of the former preparation varies from ½ to 2 drachms, and that of the latter from 10m to 3iss The fluid extract is the most eligible and effective preparation, as it contains all the virtues of its plant When combined with an equal quantity of simple syrup and diluted with a small amount of water it is not unpalatable, and will not be rejected by the most fastidious patient

Therapeutic Action—There are few remedies which possess a wider range of usefulness than geranium maculatum, and which are so devoid of harmful properties In all forms of hæmorrhage, whether internal or external, it is without a superior Hæmoptysis can usually be promptly arrested by drachm doses of the fluid extract given hourly until the attack subsides Relapses may be prevented by continuing the same dose at longer intervals for three or four days Hæmatemesis may be effectually controlled in the same manner after ergot, matico, sulphuric acid, iron, ice and other styptics have failed In hæmorrhage from the kidneys and the intestinal canal better results can be obtained from the administration of smaller doses, gtt xx four times daily, for an extended period Epistaxis may be speedily checked by plugging the nostrils with cotton dipped in a solution composed of 1 part of the fluid extract of geranium and 3 parts of water, or by syringing the nasal passages with the same solution Hæmorrhage resulting from the extraction of a tooth is occasionally obstinate in character, persisting for days, defying the cautery and other methods, enfeebling the patient and alarming the family, but it can invariably be promptly arrested by filling the socket with a piece of cotton saturated with the undiluted extract of geranium maculatum, and applying firm pressure for a few minutes Hæmorrhagia can be most effectually abated by the internal administration of geranium combined with vaginal injections of the same remedy In fewer cases it may be necessary to tampon the vagina with cotton soaked in a diluted solution of geranium or to inject the uterine canal with the same solution This latter procedure is the most effective method of arresting uterine hæmorrhage, but it must be resorted to with caution

Geranium is also of value in purpura, scurvy, hæmitidrosis, and the hæmorrhagic diathesis It is a most serviceable remedy in colliquative and chronic diarrhœa, infantile diarrhœa, and the diarrhœa of typhoid fever It may be given with marked benefit in the later stages of cholera infantum, cholera morbus, and chronic dysentery In the latter class of affections, rectal injections of the remedy appear to be most efficacious, as by this means the medicament is conveyed directly to the diseased portion of the mucous membrane This is also an effective method of eradicating ascarides

Geranium is of especial value in phthisis, restraining the diarrhœa preventing hæmorrhage, moderating the fever and night sweats, lessening the cough and promoting the appetite

In chronic bronchitis and bronchorrhœa marked improvement may be obtained from the administration of

℞	Tinct nucis vomicæ	ʒj
	Tinct sanguinaria	ʒj

Ext geranii fl	℥jss
Syr simp	℥jss

M

Sig Teaspoonful in water, every 4 hours

Chronic gastric catarrh, and the various stomach disorders due to indulgence in alcoholic liquors, can be most speedily remedied by a restricted diet, reformation of habits, and the administration of ℥ss of geranium 4 times a day

Cases of anæmia and chlorosis in which iron, arsenic, strychnine, phosphoric acid and quinine have not been of any benefit, frequently improve at once upon drachm doses of geranium before meals Amenorrhœa and other disorders of menstruation dependent upon poverty of the blood, often disappear spontaneously during a course of geranium

Aphonia due to nervousness, mild cases of hysteria, and alcohol trembling, are all benefited by full doses of geranium frequently repeated I believe that it will also be found of service in the treatment of chorea

Diluted with 3 parts of water it forms an elegant and effective gargle in relaxation of the uvula and fauces, chronic pharyngeal catarrh Applied in the same strength with a post-nasal syringe or douche it is without a superior in naso-pharyngeal catarrh When combined with an equal quantity of water it forms an excellent mouth wash in aphthæ, scurvy, mercurial stomatitis, and idiopathic softening of the gums In leucorrhœa, prostatorrhœa and chronic gonorrhœa, it may be given internally, and also used as an injection in the proportion of 1 part of the fluid extract to 10 parts of water The injections should not be used more than once every second or third day Purulent cervicitis, fissures of the cervix, and catarrh of the body of the uterus and relaxation of the vaginal walls can be cured by the application of the fluid extract of geranium, either through the medium of an injection or by the ordinary cotton tampon and application

The pain and irritation attendant upon fissure of the anus can be removed at once by touching the fissure with the undiluted extract, and a permanent cure effected by continuing the applications 2 or 3 times daily for a few days Prolapsus ani will usually yield rapidly and not recur if the pure fluid extract be brushed daily over the protruding mucous membrane, and a 25 per cent solution be injected into the rectum every second day Ulceration of the rectum and anus may be rapidly arrested by the same means The repeated application of the fluid extract will relieve the irritation and lessen the size of hæmorrhoidal tumors, and not unfrequently occasion them to shrivel up and disappear A 10 per cent solution of geranium is a useful application in chronic conjunctivitis, granular lids, and corneal ulceration The undiluted extract is without a superior in the treatment of fissured nipples It relieves the pains at once, and forms a protective covering over the painful cracks, beneath which the healing process continues undisturbed Unlike lead, and the commonly displayed agents, it is harmless to the infant, and need not be washed off before nursing

Geranium is an excellent remedy in various forms of disease of the skin characterized by excessive secretion In hyperidrosis and bromidrosis, no more effective plan of treatment can be suggested than bathing the affected parts 3 or 4 times a day with a 30 per cent solution of the fluid extract The flow of perspiration is lessened, the fœtor removed, from a state of despondency to one of comparative happiness Vesicular and purulent eczema, impetigo and pemphigus are benefited by the following lotion

℞ Extract belladonnæ fl	℥i
Extract geranii fl	℥j
Aquæ	℥ij

M

Sig Apply night and morning

The same application will be found both prophylactic and curative in intertrigo, and in eczema and herpes of the genital regions, in persons having a peculiarly delicate skin It is also efficacious in preventing the development and hastening repair of bedsores, and promoting the healing of old indolent ulcers Geranium is the best styptic in the materia medica, but it must not be expected to control the flow of blood from an incised artery It will check venous or capillary oozing, restrain the bleeding of lacerated wounds, and arrest the hæmorrhage following small incised wounds, or various minor operations, more effectually than Monsel's solution, alum, or any of the agents ordinarily employed It must, however, be applied in the proper manner To let a few drops fall on the bleeding point will not be sufficient A small piece of cotton should be soaked in the pure fluid extract and held firmly against the wounded or bleeding surface for a few minutes A piece of sticking plaster or an ordinary bandage may then be applied When this method is adopted stitches need not be inserted unless the wound is deep and the edges gaping Hæmorrhage does not recur, and the healing process begins at once and continues without interruption

Sloughing and unhealthy sores rapidly assume a healthy appearance when continually bathed with geranium Vaginal and intra-uterine injections are rarely necessary after delivery, but when the fœtor of the lochia or other symptoms demand their employment a decoction of geranium or 10 per cent solution of the fluid extract will be as efficacious as solutions of carbolic acid or mercuric bichloride, and far more safe and agreeable to the patient

Pruritus ani and vulvæ are due more frequently than is supposed to minute fissures of the skin of those regions, or to a relaxed and œdematous condition of the mucous membrane, and consequently can often be promptly relieved by the application of a strong solution of geranium

Finally, the fluid extract of geranium, owing to the large percentage of tannic acid which it contains, is a convenient and effective antidote in cases of poisoning by iodine, mercury, silver, copper, antimony, digitalis, conium, gelsemium, tobacco, physostigma, belladonna and aconite

AN INQUIRY INTO THE MORTALITY AMONG PASSENGERS ON VESSELS ARRIVING IN U S PORTS

Read in Section on State Medicine, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY S T ARMSTRONG, M D , PH D ,

PASSED ASSISTANT SURGEON U S MARINE HOSPITAL SERVICE

The question of the mortality among passengers on vessels coming to this country, aside from the cursory interest of the quarantine physician at the port of arrival, seems to have attracted but little attention—in recent years—from sanitarians at large, unless a case of infectious disease appeared at an inland city in a recent passenger on a steamship, in which case the matter became of considerable importance This was illustrated in Chicago last April, when small pox developed in an Italian who had arrived in the city April 1st, the disease appearing April 6th, he having been one of some six hundred emigrant passengers on the steamship "Alsatia," two of whom were affected with small pox *en route*

Thinking that an inquiry into this subject would develop something of interest, I have collected the laws relative to reporting mortality of passengers, and the official records of the Treasury Department concerning this mortality, and present them herewith for your consideration

The Revised Statutes of the United States require (Section 4266) masters of any vessels arriving in the United States or Territories, from any foreign port whatever, to give the collector of customs a list of all passengers taken on board the vessel at any foreign port, in which list the country, age, sex, and occupation of each passenger, and the part of the vessel occupied by each, shall be designated, also, whether any, and what number, have died on the voyage

The Statutes also prescribe (Section 4268) that in case a death shall have occurred among passengers, other than cabin passengers, over eight years of age, on board any vessel arriving in the United States or Territories, it shall be reported within 24 hours, and the vessel shall pay the collector of customs ten dollars for each of these deaths

These laws, with those regulating the number of passengers to the tonnage, the space for passengers, food, etc , cover the legal restrictions of the sanitary affairs of the vessel The enforcement of the latter laws are subject to the perfunctory (if any) supervision of a customs inspector In a paper the writer presented to the American Public Health Association (Transactions, 1885, Vol XI, "Maritime Sanitation"), the desirability of an amendment of the laws was urged, making a medical officer of the United States the inspector in such matters Who can say that instances are isolated like the French steamship Chandernagor, which arrived at New York on April 13, 1887, with 1256 Italian steerage passengers on board, one of them ill with small pox, in which complaints as to lack of food, water, and sufficient sleeping space, led to an investigation, which revealed that although the French law allowed her to carry 1300 passengers, our law (allowing one passenger to two tons) limited her to 990 passengers Though seeming irrelevant, these facts are introduced to call attention to the large population confined, for a variable time, on a vessel, and the favorable conditions for poor food or water, or over crowding, etc , to propagate contagious disease

In the "Annual Reports of the U S Marine Hospital Service," from 1883 to date, a table has been included giving the date of death, name of vessel, port of departure, sex of deceased, and cause of death, if reported, of steerage passengers From these tables the figures contained in Table I have been compiled

TABLE I —EMIGRANT DEATHS

Year	Males	Females	Total	Cause of Death, Unknown, and per cent Total	
1882	109	45	154	65	42 2 %
1883	75	37	112	10	8 9 %
1884	62	43	105	7	6 6 %
1885	50	27	77	7	9 %
1886	44	24	68	14	20 7 %

From Table I it may be seen, 1st, that the mortality among males is almost always 50 per cent higher than in females, and, 2d, that the mortality from unknown or unreported causes is from 6 to 42 per cent of the total number of deaths The first may be explained by the excess of male immigrants, the second, possibly in part to carelessness of ship's officers, but these figures are of some importance as possibly embracing deaths from cholera or yellow fever, as in several instances the vessels came from localities known to be infected Excepting one woman, from Bremen, who died of cholera September 23, 1882, no deaths of emigrants from cholera, yellow fever or small pox are reported during these five years

The small number of deaths — 516 — occurring among so large a number of emigrants, is probably due to the fact that the majority are in the prime of life This supposition is supported by the number dying in the different decennial periods of life, as shown in Table II

TABLE II —EMIGRANT DEATHS, DECENNIAL PERIODS

Age	Unknown	1 to 10	10 to 20	20 to 30	30 to 40	40 to 50	50 to 60	60 to 70	70 to 80	80 to 90
Total Deaths	5	36	43	111	107	72	68	43	29	2

These deaths are so generally distributed in various diseases that statistical tables of the cause of death would be of no advantage

Through the kindness of the Commissioner of Customs and the chief of the Bureau of Statistics, I have secured the figures, in Table III, of the number of cabin and steerage passengers brought to this country during the past five years, and the total number of deaths *en voyage* The figures for 1886 do not include emigrants from Canada or Mexico, and the cessation of Chinese immigration is to be remembered, averaging about 20,000 persons per annum It would have been an interesting accompaniment to have had the aggregate number of days these passengers were on the vessels

TABLE III

Year	Cabin Passengers	Other than Cabin Passengers	Total	Total Deaths	Emigrant Deaths	Per ct of Emigr'nts to Total Deaths
1882	121,571	747,573	869,144	578= 6⁶/₁₀	119	26
1883	118,137	594,378	712,515	465= 6⁵/₁₀	115	25
1884	124,510	524,931	649,441	392= 6 0	108	28
1885	106,362	428,647	535,009	209= 3⁹/₁₀	72	34
1886	99,090	334,013	414 303	175= 4⁹/₁₀	70	40

If we roughly estimate each passenger to have been on the vessel twelve days—rather below than above the average—we can approximate the annual mortality per thousand In Table III, in the column headed total deaths, the mortality per thousand passengers is given, six- to four-tenths of one per cent , this would give an approximate annual mortality per thousand of 18 to 12 per cent , if the passengers remained on the vessel for a year instead of one-thirtieth of that time We therefore see that though, at first glance, the mortality per thousand seems small, for the time the passengers are on the vessel, it is within four to ten per cent of the average mortality (22 5 per cent per thousand) of our American cities

One reason that the mortality should be low is, that only in exceptional cases would any passenger —either cabin or steerage—start on the voyage if ill Also the majority of immigrants, who constitute the greater proportion of the passengers, are in the prime of life, so the mortality is less influenced by the heaviest contributors to its increase in cities, those under 5 years of age and over 55

The most important fact revealed by Table III is the disproportion of the deaths of "other than cabin passengers, over eight years of age" (or emigrants), to the total deaths, varying from 25 to 40 per cent thereof Either the mortality among cabin passengers is extremely large, or there is a heavy mortality among emigrant children under 8 years of age, who are not included in the list of emigrant deaths as returned to the customs officials

When the causes of death are known an examination demonstrates nothing satisfactory, for it is not possible to ascertain, with the data now at hand, the influence of the vessel as a genetic or exciting factor in disease Such knowledge can only be obtained by the continued investigation of steamship surgeons

As from 75 to 60 per cent of these deaths are from unknown or unreported causes, it would seem desirable that an amendment should be made to the law requiring a report of the death of passengers, to the effect that the cause of death shall in all cases be specified, if known

Aside from the statistical value of such information, its utility would consist in permanently recording the mortality on each vessel, and if this was due to local causes, prompting an investigation and relegating the cause to "innocuous desuetude"

MEDICAL PROGRESS.

SURGICAL TUBERCULOSIS —In an article on this subject PROFLSSOR R VOLKMANN gives a masterly review of surgical tuberculosis, beginning with,

I *Tuberculosis of the Skin and Connective Tissue*

1 Lupus is a genuine tuberculosis of the skin, though it is to be considered a special form of tuberculosis, which attacks by preference persons who are slightly or not at all hereditarily infected Clinically it is characterized by its great tendency to local relapse, in contradistinction to other tuberculous affections of the skin Between the latter and lupus there are intermediate forms, and the prognosis of these as compared with lupus is more favorable as to local permanent cure, but worse as to later appearance of tuberculous processes in other localities, tissues and organs

2 *Tuberculous Ulcerations of the Skin*, to be distinguished from lupus, answer mostly to scrofulous ulcerations of older authors They are most frequently found in children and young persons, but are not very common if we except those cases in which they develop secondarily from tuberculous gland abscesses and tuberculous joint- and bone fistulas They are almost without exception permanently cured by surgical interference, without local relapse

3 *Primary Tuberculosis* and its *primary* tuberculous abscesses, of the deeper, especially *intermuscular, parossal* and *para articular connective tissue* layers, are very rare, and must be diagnosticated with the greatest reservation In the great majority of cases these abscesses are connected with specific bone, joint or gland affections, these forming the primary disease The present treatment of these abscesses by free incision and scraping out generally shows this relation plainly When it cannot be demonstrated on the operating table, it must not be forgotten that, particularly in bone, the tuberculous foci from which those apparently primary cellular tissue tuberculoses and para articular abscesses arise, are often exceedingly small, and may be easily overlooked, and, further, that the abscesses not infrequently appear so late that meanwhile the original bone affection is already healed

This holds particularly good for the congestion abscesses of spondylitis (tuberculous caries of the vertebral column) In favorable cases these abscesses may heal by a kind of primary union and without relapse after free incision, washing out with antiseptics, drainage and compression for a few days Out of 57 freely opened congestion-abscesses in spondylitis with gibbus formation during the last few years, 23 healed by first intention, the drains being removed after a few days This shows that the abscess was not longer supplied with pus and products of disintegration of tuberculous tissue from the bone

4 As a *primary affection* tuberculosis of the connective tissue is found chiefly in the panniculous adiposus of small children There develop at once or in rapid succession, a number of small flat knots under the skin (gommes tuberculeuses), which soon

melt and become soft, in a short time generally invading the skin over the area of the affection, so that the skin becomes bluish red, fluctuation becomes more distinct, and finally the abscess breaks For a number of years I have in my lectures called this the *furunculous form of tuberculosis of the skin and connective tissue* These abscesses heal rapidly without relapse when incised early and emptied of pus, fungous granulations adhering to the wall, and large plugs of caseated and necrotic connective tissue Sometimes, however, the process in some of the knots goes deeper instead of invading the skin, and large tuberculous abscesses form under the true skin In such a case we have to deal with a form of tuberculous cellular tissue abscess, that is neither related to diseased bones, joints and tendon sheaths, nor to affections of the lymphatic glands

5 *Tuberculous abscesses*, if they have existed for some time, whether they be primary tuberculous affections of the connective tissue, or connected with joint or bone disease, are always lined with a characteristic violet-gray, or yellow gray, opaque membrane This membrane, which is sometimes several millimetres thick, is only sparingly supplied with blood vessels, especially in the inner layers, which are constantly bathed by tuberculous pus, and contain an enormous number of miliary tubercles, by which it sometimes has the appearance of only consisting of these This abscess membrane is very easily loosened and scraped off from the surrounding tissue (basement substance), often in pieces a square inch in size The tissues forming the basement substance are perfectly healthy, being the seat of a slight reactive induration only Very rarely are the adjoining tissues invaded by diffuse tuberculous eruptions and cheesy infiltrations Only twice in more than 1000 cases of such abscesses freely opened and examined during life have I found a diffuse invasion of tuberculosis into the muscular system, which formed the wall of these abscesses When cheesy matter and diffuse cheesy degeneration of the muscular substance itself is encountered, the case is generally one of syphilis, and cheesy degenerated gummata Here the diseased tissues offer the greatest resistance to the sharp spoon, and cannot be simply torn away, or, even by considerable force, be completely scraped out The characteristic abscess membrane is wanting Both the signs mentioned here serve also in the diagnosis of actinomycotic foci, invading the muscles and sometimes resembling tuberculous abscesses

The characteristic abscess membrane is only found in tuberculous abscesses, and is therefore to be considered an absolutely reliable diagnostic sign

6 The field of the non tuberculous chronic abscesses and so called cold abscesses, as they appear during or after infectious diseases, has yet to be defined by new investigations At any rate it is much narrower than that of the tuberculous abscesses — *Langenbeck's Archiv*, Bd XXVIII, Hft 1

THE OPERATION FOR BENIGN PAPILLOMA OF THE BLADDER —KOCH reports 3 cases operated on by him

Case 1—Man, æt 40, 12 years ago first had urinary trouble, which returned again 3 years ago In 1876 a small piece of papilloma was removed with the catheter From 1879 to 1884 he appeared well After August, 1884, had pain on micturition, and passed a piece of tissue through the urethra When the patient last came for treatment he was very anæmic Examination of the external genitals and *per rectum* revealed nothing special There was severe strangury Urine acid, with much sediment Operation October 29, 1884, by median incision The end of the finger immediately came in contact with a tumor situated high up on the right wall of the bladder Supra pubic cystotomy was therefore performed, without filling the bladder, without a colporynteur, and without wounding any adjacent structures The tumor was pedunculated and as large as a hen's egg It was removed in two pieces by means of stone forceps, and the pedicle cut off with scissors Hæmorrhage was tolerably severe, but was controlled by irrigation A large drainage tube was passed through the perineal and abdominal incisions The patient made a good recovery, and 2 years afterwards there was no recurrence The tumor was a soft villous papilloma

Case 2—Female, æt 34, had complained for 3 years of burning pain on micturition, bloody urine for 15 months Since a few months back several small tumors had been passed *per urethram* On manual palpation of the vagina and abdomen a soft tumor could be felt in the region of the bladder, especially on the right side The urethra was dilated, and by Simon's mirror a tumor was seen as large as a child's fist, and attached to the right wall of the bladder by a pedicle as thick as the thumb This was cut through by means of the index finger and sharp spoon, and the tumor removed with forceps and syringing Eight days afterwards several small excrescences were removed in the same way Two years afterwards there was no relapse The tumor was a soft papilloma

Case 3—Male, æt 21, had had frequent strangury for 3 years, with sudden interruption of the stream, and bloody urine After Easter, 1885, spontaneous micturition was impossible Strong pressure removed small pieces of tissue from the bladder, and the microscope showed them to be papillomatous High fever came on, with pain on pressure in the left side The high operation was performed in June, 1885, and revealed a tumor as large as a man's fist in the bladder, attached by a pedicle to the posterior wall It was removed in small pieces, and the pedicle tied with catgut The bladder was sutured with catgut, and a permanent catheter introduced Dressing changed in 2 days, when urine leaked from the wound Fever continued down Towards the end of June an abscess formed on the left side of the rectum, which was opened externally, and fever went down At the end of July the patient was entirely well, and has remained so

With *cases 1* and *3* the number of reported operations for benign papilloma of the bladder in men now amounts to 41 Of these 19 occurred between the ages of 50 and 70, 16 between 30 and 50 The

youngest patient was 21 years old In 12 cases the tumor was seated on the fundus and posterior wall of the bladder, 10 times on the trigonum and mouths of the ureters, 5 times lateral, and 8 times on the upper wall In consistence they varied from soft villous to tough fibrous masses In all cases the symptoms were about the same The earliest was bleeding, coming on during urination, and not dependent on rest or movement In several cases small pieces of tissue were passed with the urine A further constant symptom was pain and strangury, in many cases with sudden interruption of the stream The diagnosis was made by catheterization, endoscopy of the bladder, bimanual palpation, which generally revealed small tumors, and most certainly by median section and palpation The cases show that suprapubic cystotomy is to be regarded as the normal procedure for treatment, as it alone guarantees a radical operation, that in doubtful cases perineal section is to be made, but generally only for explorative purposes —*Centralbl fur Chirurgie*, No 20, 1887

DETECTION AND REMOVAL OF EMBEDDED NEEDLES —MR H LITTLEWOOD, of Leeds, has adopted the following plan with success 1 The part supposed to contain the needle is thoroughly rubbed over with an electro-magnet, so as to magnetize the metal if present 2 A delicately balanced magnetic needle is held over the part If the needle is present, its position can be ascertained by the attraction or repulsion of the poles of the magnetic needle 3 Having ascertained the presence of a needle (e g, in the hand), the part is rendered bloodless, and a grain or more of cocaine injected hypodermically 4 An incision is made over the ascertained position of the needle 5 The electromagnet is then inserted into the wound, and with it the needle is felt for Sometimes it will be found and removed quite easily, at others great difficulty will be experienced, taking as long as one-half or three-quarters of an hour This may be due to the fact that its position has not been accurately ascertained, it may be lying across the incision, or it may be so firmly embedded in the tissues that the electromagnet is not able to withdraw it If this occurs the incision must be enlarged, and the edges held apart with some non magnetic retractors, using the electro magnet as a guide, the needle may be seen and removed with forceps If the needle is firmly fixed, the following plan has been adopted by placing the positive pole of a galvanic battery on the surface of the body, and the negative pole in direct contact with the needle, this becomes loosened by electrolysis and can then be easily removed by the electro magnet This latter method has been found useful in two cases for the removal of sewing machine needles that had transfixed the end of the finger, and were so firmly fixed as not to be removable by forceps The electrolytic action loosened the needles so that they could be removed quite easily

I have now removed six needles from the hand and a piece of steel embedded in the foot In none of the cases could I feel the piece of metal or be sure of its presence without the aid of the method above described As it requires some expensive apparatus, and sometimes takes a long time, I am afraid this method will not become general, but it is well worth the time and trouble spent if in the end one is successful, as patients really suffer a good deal of pain and anxiety if these foreign bodies are allowed to remain embedded in the tissues —*Lancet*, Aug 27, 1887

NEW METHOD OF VENTILATION —A plan for ventilating a room, which is, we think, sound in principle, has been invented by Messrs Young & Moss The ordinary fireplace is used to create a draught The outlet from the room is close to the ceiling, from this point a tube descends, making a bend at the floor level, and reaching the exit at the commencement of the chimney Between the floor bend and the exit is a cylindrical air chamber, which is said to efficiently prevent any back current into the room The apparatus can be fitted to any ordinary fireplace, and in the drawing furnished is shown in connection with the well known "country parson's" grate The ventilator is concealed by an ornamental panel, and, if uniformity be desired, a panel on the opposite side may be furnished and fitted for a coal scuttle The plan adopted by Messrs Young & Moss seems to us feasible and practicable When, however, a "ventilator" is ordered, it must always be borne in mind that an "outlet" is only half that is necessary If inventors wish their apparatus to succeed, they must insist on properly placing inlets also If this be not done, in proportion as the outlet is efficient so will the cold air come whistling under doors and through cracks and keyholes, and the use of one or other device for the "exclusion of draught" will be the inevitable result —*Lancet*, October 1, 1887

QUEBRACHO AS A TOPICAL APPLICATION —BOURDEAUX calls attention to this use of quebracho He uses the alcoholic extract diluted with water He finds it an energetic astringent and a promoter of cicatrization In burns in the stage of granulation it is preferable to iodoform In crushed and lacerated wounds healing takes place without the production of pus or symptoms of inflammation under the influence of a few applications of the quebracho solution When applied to a wound it dries quickly, leaving a deposit or covering under which healing goes forward rapidly It may be taken internally advantageously in dysentery (20–30 drops) In endometritis and ulceration of neck of womb it is valuable, one teaspoonful being dissolved in large cupful of water and used as an injection It is peculiarly useful, taken internally, in asthenia —*Centralblatt fur Chirurgie*, No 41, 1887

OIL OF SASSAFRAS AND IODOFORM —According to MR C E DODSLEY the addition of gtt iv of oil of sassafras to ℥i of iodoform completely covers the disagreeable odor of the latter, and the odor of the oil itself is not noticeable —*New York Med Journal*, Oct 8, 1887

KREATIN AND KREATININ —ARE THEY WASTE OR NUTRITIOUS PRODUCTS IN THE ORGANISM ?

This question is of interest not alone from a purely physiological point of view, but also from the clinical standpoint, since the substances are part of the extractives of beef extracts, and may play an active part in rendering the latter nutritious and stimulating Kreatin is known to increase in muscle when it is made to contract Kreatinin is found in the urine, where its amount increases when injected into the blood It is also found in larger quantities in the renal secretions when a person lives upon meat than when upon a purely vegetable diet Its quantity is also increased in acute diseases and in chronic anæmic disorders, and is diminished in convalescence

Chemists generally assert that both of these substances are formed in the organism by oxidation of proteids, and that they are substances formed as intermediate products of the final conversion of proteids into urea, carbon dioxide, water, etc They have therefore been regarded as waste products Dr T J Mays[1] has asked, however, the question with which we began these remarks He was led to it from a study which he prosecuted to determine the nutritive and stimulating value of beef extracts This he found considerable even when the amount of albumen present was so small that it could hardly be the active agent in them He sought, therefore, in the extractives for some nutritive substances The extractives of beef extract are chiefly kreatin, kreatinin, sarkin, xanthin, carnin and inosite To test their nutritive and stimulating power he made use of the frog's heart in the following way When a 6 per cent saline solution is passed through the heart it gradually ceases to beat Water, acids and alkaloids do not revive it, but blood, milk and beef extract will cause it to renew its wonted rhythmical movements So also, and to fully the same extent, kreatin and kreatinin are found to stimulate and nourish the heart muscle Dr Mays found that "after working for many hours with a frog's heart, and after it became so thoroughly exhausted as to refuse to respond any longer to the stimulant action of blood, the transfusion of kreatin or of kreatinin *in the* proportion of one part to one or two thousand parts of saline solution would at once spur it on to renewed contractions, which were continued for some time longer "

Sarkin and xanthin have to a very limited degree the same action upon the heart muscle The other extractives of beef extract are without activity

Although asparagin, theïn and caffein are very similar to kreatin and kreatinin in chemical composition, the former substances do not possess the power of exciting and recuperating the wearied heart muscle

These facts lead us to look upon kreatin and kreatinin as substances of nutritive value And the character and degree of stimulation of the heart muscle by them so exactly corresponds to that of beef extract solution that we must look to them as the active stimulating principles of this solution

The author does not reason further in regard to the nature of these substances, but their behavior suggests to us the query, whether kreatin and kreatinin are not the products of cellular action on the albuminous substances in the blood and interstitial spaces, products prepared by the tissues for their own use, and representing a part of the intimate constructive changes that food undergoes after solution in the alimentary tract and introduction into the blood

[1] "The Physiological Action of Kreatin Kreatinin and their Allies" By Th J Mays The Practitioner October 1887

THE DEATH OF VON LANGENBECK

In the death of PROFESSOR BERNHARD VON LANGENBECK the surgical world has sustained a most severe loss, and thousands of his pupils, in every land, will deplore the stroke that has removed one of the greatest surgeons of all time And his pupils, those whom he has taught, are not only those who have learned from his lips, but every surgeon may justly claim to have been taught by him In the words of a well known German surgeon "Langenbeck was one of the first surgeons of the new era,

genial and inventive, a masterly operator, a fine therapeutist, beyond comparison in personal experience, of inexhaustible perseverance" He devised many new operations and improved many old methods of operating, and his contributions to conservative surgery by the use of resections, subcutaneous osteotomies, osteoplastic operations and tenotomies are alone sufficient to have given him a lasting reputation

Von Langenbeck was born at Horneburg, in Hanover, in 1810, and was graduated from the University of Gottingen in 1835 Shortly after this he established himself in Gottingen as Privat-Docent in physiology, and began to practice surgery Soon afterwards he was made Professor Extraordinarius, and in 1842 he went to the University of Kiel as Professor of Surgery and Director of the Friedrichs Hospital In 1848 he became connected with the army, and directed the surgical department in the hospitals during the war of the Duchies against Denmark In this year he was called to Berlin to succeed Dieffenbach, becoming, at the age of 38, Professor and Director of the Berlin Royal Surgical Clinical Department, the greatest surgical clinic in Germany His reputation was in a great measure made by the ability displayed by him in the three wars against Denmark in 1864, Austria in 1866, and France in 1870 He was ennobled by the King of Prussia after the Danish war in 1864

Sir William McCormac, who became acquainted with him during the Franco-Prussian war, says He was not less beloved as a man than renowned as a surgeon and teacher The surgical professors in most of the great Universities (W Busch, Wilms, von Bergmann, Nussbaum, Billroth, Volkmann, Socin, Konig, Schoenborn, Trendelenburg and others) have been among his favorite pupils and assistants, so that the influence of his teaching has spread far and wide Personally he was beloved in a rare degree as a man of spotless honor, sympathetic and affectionate, and with the warmest domestic affections Mainly through his example did conservative surgery obtain a sure footing in military practice His results in regard to excision of joints, especially the ankle and wrist, are most remarkable, and his keen observation told him the frequent possibility of saving the limb when the knee had been perforated by gunshot None could be more dexterous as an operator He was bold beyond most men, and his knife was always guided and controlled by profound anatomical knowledge He possessed a capacity for work which was simply astonishing His habit was to rise at 4 every morning, drink a cup of coffee which he made himself, and begin his literary work

In 1860 he started the *Archiv fur klinische Chirurgie*, commonly known as Langenbeck's *Archiv*, and edited it, with the assistance of Billroth and Gurlt, up to the time of his death In this may be found most of his numerous contributions to surgical literature It was through his efforts that the Association of German Surgeons was formed He was chosen its first President, the office being an annual one, but at the end of the year he was re-elected, and was finally made perpetual President Five years ago his failing health compelled him to remove from Berlin to Wiesbaden, and the remainder of his life was spent in the beautiful home which he built for himself on the slope of the Nersberg Not long since he submitted to operations for cataract, which seemed to be successful He died of cerebral apoplexy on September 29, and on October 5 was buried by the side of his wife in the cemetery at Berlin

"A great and rare man is gone," says Guttmann, "gone the eminent teacher, the great master, the Nestor of German surgery, the ornament of our State and University, where thousands have sat at his feet and received instruction from his lips"

INDIRECT AND IMPROPER ADVERTISING

We frequently receive from some of those who have advertisements in the advertising pages of THE JOURNAL, printed slips ingeniously calling attention to the value or peculiar quality of one or more of the articles they advertise, couched in such phraseology as to appear to have been written by the editor of THE JOURNAL, accompanied by a request to give such slips a place in the columns of THE JOURNAL for reading matter We have uniformly refused to use such slips, and for the following reasons 1 In making a contract with an advertising patron for a given space in the advertising columns and for a certain sum, there is no condition either expressed or implied that he shall have any additional space in any other columns not devoted to advertisements 2 If we should accept such slips and place them in our reading columns as though they were expressions of our own opinion concerning this or that article, when they were actually only the interested expressions of the manufacturers or advertisers themselves, we would be practicing a direct fraud upon our readers This reason alone, is abundantly sufficient to deter us from yielding to any such use of our columns Not a few enthusiastic manufacturers of medicines, formulas, foods, etc , appear to think we should ac

tually test by clinical use every new thing, and every new combination of old things, they choose to send us, and express either by certificate or through the columns of THE JOURNAL, our most gratifying approval It seems never to have entered into the thoughts of such parties, that such a task would require us to devote *all our time* to that work, and make *all* our patients subjects for *experimental* dosing, leaving us neither time to edit THE JOURNAL or even to tabulate the results of our heterogenous experiments on suffering humanity

It is proper for physicians to use cautiously and judiciously such new remedies as may reasonably be presumed to possess valuable properties in the treatment of disease But to obtain reliable results, such use must be extended through a large number of cases, the correct diagnosis of which has been assured, and only an actual clinical record of such cases becomes appropriate and desirable material for the reading columns of medical journals

THE DEATH OF FREDERICK HYDE, M D, Professor of Surgery and Dean of the College of Medicine of Syracuse University, N Y, was announced Oct 17, 1887, at the age of 80 years The deceased had long been known and recognized as one of the most honorable and intelligent members of the profession in the State of New York The following report adopted at a meeting of the Faculty of the Syracuse University, on the evening of Oct 17, correctly voice the sentiments of all who have the pleasure of an acquaintance with Professor Hyde

In the full possession of his mental faculties, with eye undimmed and natural strength unabated, our beloved dean, Dr Frederick Hyde, at the advanced age of four score years, has been called from his life of incessant unselfish labor to his rest and eternal reward

As colleagues we unite in mourning his loss with that large community where he was revered for his unswerving integrity and his active devotion to the best interests of society, with the church of which he was a consistent and influential member, and with his stricken family who, while they miss with anguish, remember with gratitude and pride, his affection, his kindness, his sterling character and that "purest treasure mortal times afford, a spotless reputation"

Extensively known by his valuable contributions to surgical literature, and by his early and continuous advocacy of a higher standard of medical education, Professor Hyde was a prominent founder of our University College of Medicine, and he has worthily filled the office of dean since the beginning, fifteen years ago

His associates and the students in the medical school which he loved and to which he devoted so much valuable time, will miss his gentlemanly presence, his genial manner, his wise and encouraging counsel, and his learned teaching

We all bear ready and unreserved testimony that his influence has always been salutary, at once a stimulant and a benediction

As a slight token of our respect and affection, we will follow his mortal remains to their resting place to morrow

H D DIDAMA,
WM MANLIUS SMITH,
W F PLANT

GLEDITSCHINE OR STENOCARPINE —Investigations of specimens of this new remedy, obtained from Messrs Lehn and Fink, of New York, at the laboratory of Messrs Parke, Davis & Co, appear to prove the said remedy to contain 6 per cent of cocaine and probably some sulphate of atropia, while the leaves of the Gleditschia triacanthus, from which the stenocarpine is supposed to have been derived, contains but a very small quantity of an alkaloid, and that without active anæsthetic properties Is the new remedy an attempted imposition upon the medical profession?

SANITARY CONVENTION AT ALBION, MICHIGAN —A Sanitary Convention, under the auspices of the Michigan State Board of Health, will be held at Albion, on Tuesday and Wednesday, Dec 6 and 7, for the discussion of important topics relating to the sanitary interests of the people Citizens generally are invited to attend Prof Delos Fall is Chairman of the Local Committee, and Dr H D Thomason, of Albion, Secretary

A NAVAL MEDICAL EXAMINING BOARD is now in session at the Naval Hospital, Philadelphia, Penn, for the purpose of examining candidates for admission to the Medical Corps of the Navy Circulars of information can be obtained on application to the President of the Board There are twelve vacancies in the list of Assistant Surgeons

DISTRICT MEDICAL SOCIETY OF CENTRAL ILLINOIS —This Society will hold its Semi-Annual Meeting at Vandalia, Ill, on Tuesday, Nov 1, 1887 An interesting programme of work has been provided

DR JAMES KNIGHT, Surgeon-in Chief of the Hospital for the Ruptured and Crippled, of New York, died on October 24 after a brief illness He was the founder of the Hospital He was born in Maryland in 1810, and was graduated from the Washington Medical College of Baltimore in 1832

SOCIETY PROCEEDINGS.

ST LOUIS MEDICAL SOCIETY

Stated Meeting, September 21, 1887

THE PRESIDENT, S POLLAK, M D IN THE CHAIR

DR WALTER COLES read a paper on

POSTHUMOUS DELIVERY

In considering the subject of post mortem delivery, several questions of practical importance naturally present themselves, which we will endeavor briefly to consider

1 As to the power of the child to survive somatic death of the mother, and the duties and responsibilities of the medical attendant in cases of sudden death of the mother at or near full term

2 As to the capability of the uterus to contract and expel its contents after death

3 The effect of gaseous distension, the result of decomposition, as an expulsive force

The second and third of these inquiries are chiefly interesting in a medico legal point of view, but the first is an eminently practical one, of grave importance, which may suddenly confront any one of us, at any moment, and from its very nature, will require prompt and decisive action Cases are not rare where from heart clot, or other causes, women have died in labor, or at an advanced stage of pregnancy In such an emergency, actual death being assured, the question of saving the child naturally arises, and the physician should be possessed of such knowledge as will direct him when and how to act under these trying circumstances

All obstetrical writers agree that the fœtus may survive the death of the mother for a certain length of time, and it is also a well known fact that an immature child will retain its vitality longer than one at full term Numerous instances are recorded in which living children have been extracted, both by turning and the Cæsarean section, after the death of the mother Blundell mentions the case of a woman who was run over by a car, which crushed the liver and produced instant death The dead body was taken into the hospital near by, when, seeing that she was in an advanced stage of pregnancy, the abdomen was opened and a child delivered, which, though apparently dead, he succeeded in resuscitating The same author relates the still more remarkable case of a pregnant heifer, whose uterus was opened three-quarters of an hour after death and a living calf extracted I well remember hearing my father say that he had reared a fawn which he had cut from the uterus of a dead doe It may be remarked here that the lower animals are said to perish sooner in utero than the human subject

Authors differ widely as to the length of time at which asphyxia may be overcome and the child restored Most of us have doubtless seen resuscitation take place after the lapse of many minutes, and hope should never be abandoned as long as there is the slightest heart beat Most cases prove hopeless after fifteen minutes, but the numerous authenticated exceptions, where respiration has been established after much longer periods have elapsed, should encourage persevering effort, and lead us to give the child the benefit of the doubt in all cases where the death of the mother is well established It is probable, owing to the temperature of the mother's body, that the asphyxiated child will retain its vitality much longer within the uterus than outside of it Aveling believes that the child may thus survive in the womb many hours after the death of the mother Villeneuve, in a published paper in 1862, reports a number of cases in which it was ascertained that children survived during astonishly long periods Four were saved by the immediate performance of the Cæsarean operation Five were extracted alive after a lapse of ten to thirty minutes Two children were saved after the mother had been dead two hours, one after two and a half hours, one after three hours, and one after four and a half hours In referring to these latter cases, Tarnier remarks "Although the operation is generally useless at a later moment, it ought, nevertheless, to be performed, because some cases, whose authenticity I cannot vouch for, would seem to prove that the child's life may remain intact for ten, fifteen, or even twenty-four hours" Charpentier, one of the latest French authorities, is disposed to discredit these cases, however, and claims that none of them are sufficiently authentic to merit belief

In all cases when it becomes necessary to effect post-mortem delivery we have the choice of two methods we may resort to hysterotomy or else to forcible delivery through the natural passages When death occurs during labor, and we find the os well dilated or dilatable, we may readily perform version, or if the head be within reach, forceps may be applied The distressing circumstances requiring either operation will often prompt friends to interfere, and prevent any interference on the part of the physician His duty, however, is plain, and nothing should deter him from at least urging an immediate operation if he is satisfied that the woman is dead, and that there is hope for the child By far the simplest and safest method of rescuing the child is by laparotomy, but this may be interdicted by friends who, at the same time, might not object to an attempt *per vias naturales* In choosing between these methods of delivery it should not be forgotten that several instances are recorded in which the terrible blunder has been committed of opening women who were not really dead.

Some writers have gone so far as to advise a resort to forcible delivery whenever the mother is *in extremis* Such an idea, however, except under peculiar circumstances, is revolting, and should be repudiated We quite agree with Charpentier when he says, should the woman be *in extremis* "Respect her condition, and do not hasten her end by maneuvers which may not save the child Once the mother is dead, however, act quickly in the interests of the child

In *accouchement force*, we should not lose sight of the fact that the uterus is endowed with the power of independent contraction after death, a property which greatly aids the physician in effecting delivery, notwithstanding he is deprived of assistance through

the cerebro spinal system Where the pelvis is ample, he may overcome any rigidity or resistance in the soft parts, if necessary, by free incisions It is a recognized fact that the body of the uterus is under the dominance of the sympathetic, while the chief supply from the cerebro spinal system of nerves is distributed to the cervix and external os The effect of somatic death, therefore, is to paralyze the latter class of nerves, and hence to produce a relaxation of the outlet to the womb, rendering those parts readily dilatable, and thus, in many cases, preparing the way for artificial delivery

As to the influence of death upon the uterus, the fact that the womb does not cease its muscular activity when the vital spark departs from the body is so well known as scarcely to need an argument Dewees says "However much this circumstance may excite our surprise, or challenge our belief, it is, nevertheless, authenticated by various testimony" We may add that this power of post mortem contraction has been observed repeatedly in lower animals, as well as in the human subject Harvey observed it in the doe, William Hunter in the cat and rabbit, Mueller noticed it in the uterus of the rat and oviduct of the turtle, while Tyler Smith has seen it in the guinea pig and other animals It has been observed in women in very numerous instances where the Cæsarean operation has been practiced shortly after death, and also where the hand has been passed into the uterus for the purpose of turning or delivery of the afterbirth Montgomery, Levret and others cite cases in which the uterus not only contracted down upon the child during artificial delivery, but in which it was subsequently difficult or impossible to introduce the hand for the purpose of securing the placenta These facts would indicate that the uterus is capable of exerting a very powerful influence in the post mortem expulsion of its contents, a force which has been variously estimated at from five to eighty pounds True, in most of the computations of this power in the living subject, it has been difficult to eliminate the factor of coordinate muscular assistance, but when we come to reflect that paraplegic women have brought forth children, we must concede that parturition is mainly accomplished by uterine effort Playfair adduces a most practical and conclusive argument in support of this position He says "There are many facts in the history of parturition which make it certain that the chief factor in the expulsion of the child is the uterus Among these may be mentioned occasional cases in which the action of the abdominal muscles is materially lessened, if not annulled—as in profound anæsthesia, and in some cases of paraplegia—in which, nevertheless, uterine contractions suffice to effect delivery The most familiar example of its influence, however, and one that is a matter of everyday observation in practice, is when inertia of the uterus exists In such cases no effort on the part of the mother, no amount of voluntary action that she can bring to bear on the child, has any appreciable influence on the progress of labor, which remains in abeyance until defective uterine action is reestablished, or until artificial aid is given" We thus see that while, in the dead woman, the power of uterine contraction is temporarily preserved, the rigidity in the soft parts, through which the child has to pass, is reduced to a minimum, the tendency being to push the fœtus in the direction of least resistance

This brings us to the consideration of spontaneous post mortem parturition, a phenomenon which is now recognized by universal obstetrical authority Dilatation of the os and the commencement of labor is often excited *in articulo mortis*, as has been demonstrated both in the human subject and in the lower animals This tendency to the precipitation of the parturient process in the dying is doubtless greatly modified by the mode of death Many diseases and accidents, such as coma, apoplexy, cholera, or in fact any condition tending to deoxidize the blood, will promptly excite uterine activity Such being the condition of things at the moment of death, the occurrence of *posthumous* extrusion of the fœtus should not be a matter of surprise, when we reflect that the uterus is capable of vigorous post mortem contraction, that the uterine contents are subjected to *rigor mortis*, and finally to very powerful gaseous pressure, the result of decomposition This latter must prove a most important factor, especially in cases of early pregnancy At a recent inquest held in this city upon the body of a young woman, far advanced in decomposition, the uterus was found inverted and protruding from the vaginal outlet, while a fœtus of about three months, with its membranes, was discovered in the clothing cut from the corpse This case has created some controversy, but it would not seem to be unique, since, as Tyler Smith remarks "Cases are related in which the fœtus has apparently been expelled some days after the death of the mother by gaseous distension of the abdomen" Tidy, in his "Legal Medicine," vol i, p 85, says "It is recorded that gases generated in the abdomen have been sufficient to force fæces from the bowels, urine from the bladder, and even a fœtus from the uterus" Montgomery remarks that "The occurrence of delivery after the life of the mother has become extinct, and consequently effected by the independent contractile power of the uterus, has been attested by so many authors of established credit, that we cannot refuse it our belief, having received the testimony of Fodéré, Buffon, Leroux, Levret, Baudelocque, Bichat and others" Prof Hermann, of Berne, relates the following case in point "On the third day after the death of a young woman who was in the sixth month of pregnancy, the nurse heard a loud noise proceed from the corpse A physician was immediately sent for, who on his arrival, found the deceased had brought forth twins, which were enclosed in a membrane quite entire, and not in the least putrid The placenta only appeared to have suffered from the effects of putrefaction"

In a discussion of this subject before the Medico-Legal Society of Paris, Pinard related the case of a young woman who died in July, 1872, at about the fifth month of pregnancy When the body was raised to be placed in a coffin thirty six hours after death, a fœtus fell from between the legs of the corpse On examination the uterus was found inverted and pro-

truding from the vaginal outlet, with the placenta still adherent In the Transactions of the London Obstetrical Society for 1872, Dr Aveling reports thirty cases of posthumous birth In one of these cases the child was born alive The same writer concludes as the result of his investigations, that the uterus may expel its contents after death even though there be no preexisting symptoms of labor, also that expulsion of the placenta, evolution of the fœtus prolapse, inversion and rupture of the uterus may all take place post-mortem

As before remarked, these cases are chiefly interesting as matters appertaining to medical jurisprudence But they are not difficult to explain when we consider the various forces which are brought to bear upon the uterine contents both at the moment of death and subsequently thereto And it is quite likely that could the grave reveal its secrets, instances of spontaneous post-mortem parturition would be found far more frequent than is generally supposed

By no means the least interesting feature connected with posthumous delivery is the occasional occurrence of inversion of the uterus When this condition was first called to the attention of the profession, it was looked upon as a very remarkable phenomenon, not likely to occur spontaneously, and hence signifying some suspicious outside interference This was the interpretation hinted at by Pinard in the case related by him before the Medico Legal Society of Paris, and endorsed by Taylor in his well known work on "Medical Jurisprudence" But now that there is other authority for believing that inversion can occur spontaneously, even in the earlier months of pregnancy, we are compelled to seek an explanation in the physical conditions which naturally follow death and attend upon decomposition and gaseous distension of the abdomen We have already seen that the immediate effect of somatic death is to relax the circular bundle of muscular fibres which surround the cervical zone of the uterus, while the muscles of the fundus and body retain their activity, the effect being to force the body of the organ down through the patulous and passive os and cervix, thus according exactly with the *modus operandi* of this accident in life, as elucidated by Prof Isaac E Taylor, of New York, when he declares that "spontaneous active inversion of the uterus rests upon prolonged natural and energetic action of the body and fundus, the cervix, the lower part, yielding first, is thus rolled out, or everted, or doubled up, as there is no obstruction from the contractility of the cervix, which is at rest, or functionally paralyzed, the body is gradually, sometimes instantaneously, forced lower and lower, or inverted"

Even where inversion is not completed during the period of active contraction of the fundus and body of the uterus immediately following dissolution, it is quite easy to conceive that the process may be thus commenced, and a physical condition brought about which would render complete inversion of the organ both natural and easy, as the result of the pressure brought to bear through subsequent decomposition upon its flaccid and yielding walls

NOTE —Since reading the foregoing paper, Dr M H Post has informed me that in 1872, while he was an *interne* at the Female Hospital in this city, a case of post-mortem parturition occurred at the institution, a case which bears out the point I make, that uterine contractions are frequently excited *in articulo mortis* In this instance a woman about seven months advanced in gestation died of acute pneumonia There were no symptoms of labor prior to death, but a short time afterwards it was discovered that a child had been born, which breathed a few times after being expelled

AMERICAN GYNÆCOLOGICAL SOCIETY

Twelfth Annual Meeting, held in the Hall of the Academy of Medicine, New York, September 13, 14 and 15, 1887

(*Concluded from page 538*)

THURSDAY, SEPTEMBER 15,—THIRD DAY

DR A MARTIN, of Berlin, said that the principal objection to the dropping of the pedicle is the danger of hæmorrhage This danger he thought did not exist In Berlin it is the practice to treat the pedicle with Esmarch's constricting apparatus In removing the body of the uterus, a V-shaped excavation is made in the cervix The upper portion of the cervical canal is then dissected out, and the lower portion carefully disinfected The cavity thus formed is brought together with sutures Next the two flaps of the cervix are united, and then the edges of the peritoneum are brought together In this way danger of hæmorrhage is avoided He thought that the method of fixing the pedicle will have little influence on the development of sepsis Many of these patients die from the effects of their disease The intra-peritoneal method of treating the pedicle is certainly the ideal method Up to the end of 1886, he had had 84 supra-vaginal amputations of the uterus Of this number 10 died of sepsis and 17 died of collapse following embolism This series included a number of very unfavorable cases Of his last 30 supra-vaginal hysterectomies he had lost three

DR A R SIMPSON, of Edinburgh, thought that we could not say that either method of treating the pedicle is the best in all cases Each case must be decided by the conditions met with in that particular case He thought that in the treatment of fibroid tumors the clamp would hold its ground, for the reason that in this way the pedicle can be secured in a much shorter time, and this is an important point Dr Bantock had objected to the use of iron He agreed with him that the solution of the perchloride should not be used, for it is difficult to confine a liquid to the desired point, but the persulphate in the form of a powder does not offer this objection He had used this in combination with iodoform and bismuth powdered over the stump with entire satisfaction

DR H MARION SIMS, of New York, had employed the extra-peritoneal method in the hysterectomies which he had performed He had seen his father

employ the intra peritoneal method with such unfavorable results that he had feared to try it He had had eight cases, of which two died of sepsis the result of sloughing of the stump

Dr Mathew D Mann, of Buffalo, had had six cases in which he had removed the uterus or fibroid tumors from the uterus In the first case where he removed a fibroid tumor weighing fifteen pounds, he encircled the pedicle with a ligature and dropped it Six hours later the woman was in a state of collapse from hæmorrhage He opened the abdomen and secured the pedicle with a wire clamp and the woman recovered Since then he has always used the clamp All his cases have recovered in the after treatment of the stump He rubs it with iodoform, packs cotton around it, and leaves it exposed to the air In this way it dries quickly and becomes perfectly hard

Dr Bantock in closing the discussion, calls attention to the fact that while his mortality from the extra peritoneal method of treating the stump had been 12 in 72 cases, that of Dr Martin in the intra peritoneal method had been 27 in 84 cases The number of cases is, however, not large enough to be of much value The proportion of septic cases with the intra peritoneal method was greater than with the extra peritoneal method

Dr Robert Battey, of Rome, Georgia, read a paper on

BATTEY'S OPERATION, ITS MATURED RESULTS

In August, 1872, the author performed his first operation for the removal of the functionally active ovaries for the relief of otherwise incurable troubles Up to the present time there have been no statistics as to the ultimate effect of the operation Reports have been given showing the immediate results, but none showing the results on the affection for which the operation was performed All the cases reported in this paper had been traced carefully up to the present time, they were all the subjects of a complete Battey's operation, and had all been operated on a year or longer The following conclusions were presented

1 The change of life is the most important factor in securing the complete result of this operation

2 In exceptional cases the cure almost at once follows the operation, but in the vast majority of cases the patient must pass through the ups and downs incident to the change of life before the restoration to health is complete

3 The length of time required to pass through the nervous and physical perturbation attendant upon the change of life is variable It may be one year or it may be three or five years

4 Of the cases operated on a few were, no doubt, badly selected, and the proper selection of cases is a problem yet to be solved

5 Patients who have become addicted to the habitual use of morphia, opium, chloral or alcohol, cannot be restored to health until the pernicious habit is abandoned

6 Cases which are the proper subjects of this operation if allowed to suffer eventually, reach a stage where they became absolutely incurable by any operation

7 In a number of cases the patients were in no wise benefited by the operation In several of these the indications seemed clear and unmistakable

8 In some cases neuralgic pain remained How much this was due to an unabsorbed ligature was a question to be considered

9 A careful analysis of the cases seems to show that the removal of the tubes with the ovaries had no influence in the establishment of the menopause, the only effect of their removal being on the disease of the tubes themselves

10 The operation is not an infallible one The percentage of failures recorded is a notable one, but when it is remembered that the cases included are only those otherwise incurable, each case cured is a positive gain A like percentage of cures in cases of cancers of the uterus or of cancer of the breast would be an achievement of the greatest magnitude

Dr A W Johnston, of Danville, Ky, read a paper on

THE INFANTILE UTERUS

He called attention to the fact that the uterus was composed of two distinct portions, the body and the neck, the relation between the two being almost the same as that between the stomach and the pylorus The non development of the uterus may result from various causes such as injury, etc The growth and function of the endometrium was referred to at length The author had discovered a branch of the sympathetic nerve entering the uterus and the attachment of the Fallopian tube, and he thought it probable that the uterus received its physiological orders He held that it was not the removal of the ovaries and and tubes that brought on the change of life but it is the neurotomy which the removal of these organs necessitates From this he argued that the arrest of the growth of the uterus was in all probability due to interference with this nerve supply An acute neuritis may often pass unrecognized One of the most marked symptoms in these cases is pain resulting from the efforts of the endometrium to perform a function for which it is not capable In the management of these cases it seems that in some of the simpler ones a certain amount of benefit is derived from the use of stem pessaries and from galvanism In the majority of cases of corporeal deficiency he considered it undesirable to induce the menopause, but in some cases where the ovaries remain large and tender this operation may be resorted to In conclusion the author said "if we wish to have a clear idea of the physiological position of the uterus we must emancipate it from the thraldom of the ovaries in whose secure grasp it has been held for the last fifty years "

Dr R S Sutton asked if Battey's operation consists in the removal of the ovaries alone and if in the 54 cases reported the removal of the ovaries alone brought on the menopause in 50 cases?

Dr Theophilus Parvin asked Does Dr Battey find the ovaries invariably diseased and how often is there associated disease of the tubes?

DR LLOYD ROBERTS, of Manchester, England, asked Dr Battey as to the condition of the uterus in the cases reported

DR WM M POLK asked what is the condition of the ovaries that demands removal? Can we after the abdomen is opened, tell by the appearance of the ovaries whether they should be left or removed?

DR BANTOCK said that he had always understood Battey's operation consisted in the removal of the perfectly normal ovaries He asked if this is the correct idea

DR BATTEY, in replying to the various questions, said that he did not restrict the term Battey's operation to the removal of the ovaries The removal of the ovaries is not a necessary constituent of the operation Battey's operation consists in the induction of the menopause, no matter in what way it is brought about The removal of the ovaries does not always bring about the menopause, the removal of the ovaries plus the tubes, does not invariably cause the menopause, the removal of the ovaries plus the tubes, plus the uterus does not always bring about the menopause In his experience the ovaries are always diseased, but this is simply an accident of the operation, the operation is not done for the removal of diseased ovaries Battey's operation is not normal ovariotomy He entirely repudiated that term As a rule he removes only the ovaries, but in a small proportion of cases he removes the tubes, but only when the tube is the seat of positive disease such as pyo salpinx or hydro salpinx The condition of the uterus varies in each case He does not insist upon visible changes in the ovary to justify its removal but rests for his justification on the urgent necessities of the case and on the fact that nothing else effective has been proposed He does not operate until all other measures have failed

DR THEOPHILUS PARVIN, of Philadelphia, read a

NOTE ON THE IMPORTANCE OF THE USE OF ANTISEPTICS IN PRIVATE OBSTETRIC PRACTICE

The question as to the necessity for the use of antiseptics in hospital practice has been settled, but private practice their use is often omitted, chiefly perhaps on account of the trouble and expense involved The puerperal woman should be as carefully treated in private practice as in the hospital ward While an obstetrician may attend many cases of confinement without a death from septicæmia yet he may have had many cases in which the woman had been crippled as a result of this affection The day is coming when if a case of puerperal septicæmia occurs in the practice of an obstetrician who does not employ these precautions he cannot escape the censure of his professional brethren or of his own conscience In order to facilitate the use of these agents the author had prepared a small case containing articles often required in the treatment of a case of confinement The case contains corrosive sublimate tablets, strong silk for ligating the cord, antiseptic catgut, laudanum, ergot, carbolic acid and tablets of per sulphate of iron There is also a flexible catheter, tenaculum, laryngeal tube, needle holder, scissors, lancet, needles and silk-worm gut for closing tears of the perineum and within the vagina

DR LAWRENCE, of Manchester, Eng, pursues the following plan During the progress of the labor the vagina is several times washed out with a warm solution of carbolic acid 1 200 Within half an hour after the removal of the placenta he inserts a suppository of iodoform containing 25 grains This is then used night and morning and the discharge remains inoffensive

DR A R SIMPSON, of Edinburgh, called attention to the value of turpentine in cleansing the hands Even after the examination of a case of cancer the use of turpentine will render the hands perfectly clean

DR REED, of Glasgow, said that he never examines a woman without using antiseptics He carries in his pocket papers containing 10 grains of the bichloride of mercury and dissolves one of these in a pint of water and uses in for washing his hands As a lubricant he uses a preparation consisting of 3 parts of pure soft soap, 1 part of glycerine, and 5 per cent carbolic acid This is kept in a collapsible tube such as painters use

DR HOWARD A KELLY, of Philadelphia, is in the habit of carrying corrosive sublimate put up in gelatine capsules containing 7 grains This will readily dissolve in hot water or the capsule may be opened and the corrosive sublimate added to the water

DR EIY VAN DE WARKER, of Syracuse, N Y, read a paper on

EXTRA-UTERINE PREGNANCY AND ITS TREATMENT BY ELECTRICITY

The following case was reported Mrs X, æt 27 years, was married at the age of 24 In 1885 she had an abortion at three months July 25 she had her last menstruation and August 28 she was taken with severe pain beginning in the pelvis and extending over the abdomen There was slight collapse which disappeared under the use of morphia The next day what was taken for menstruation came on The attacks of pain continued to recur, and on September 17 the decidua was passed On examination a small tumor was detected to the right side of the uterus and slightly posterior to it This was about 3 inches long and 1½ inches in diameter Extra uterine pregnancy was diagnosed Severe paroxysms of pain continued to recur, and on October 6 the electrical treatment was commenced This consisted in the use of the faradic current, a strong induction coil being used The patient was given ten treatments of half an hour's duration, one electrode being pressed against the tumor in the vagina and the other applied externally At the end of this time there was no apparent change in the pelvic mass, and the pain continued On October 20 the treatment was continued one hour, and this was repeated on the following days until three applications were made After the first of these applications the tension of the cyst was found to be less This was regarded as a sign that the fœtus was destroyed, and was believed to be a sign easier of recognition than a diminution in the size of the tumor The paroxysmal pain also

ceased as soon as the tension diminished In using electricity for this purpose the applications should be repeated until the subjective and other evidences of pregnancy disappear In this case the patient recovered completely but it was seven months before all traces of the tumor had disappeared

Dr John C Reeve, of Dayton, O, had reported one case of extra uterine pregnancy cured by electricity Twenty years ago it was pointed out that sudden and violent attacks of pelvic pain attended with gushes of hæmorrhage almost certainly indicated extra uterine pregnancy We have since learned that the expulsion of a deciduous membrane is pathognomic In the diagnosis of this condition the first thing to do is to determine the probable existence of pregnancy An important point in diagnosis is that the tumor in the pelvis manifests signs of activity in its circulation and it grows rapidly

Dr H Marion Sims reported a case under his care four years ago in which treatment by electric shock was resorted to The patient was anæsthetized and twenty or thirty shocks from fifteen freshly charged cells were passed through the fœtal mass Eight or ten applications of this kind were given at intervals of two or three days At the end of this time there was noticed a decided lessening in the tension of the sac The use of electricity was then stopped At the end of one year there was still some thickening of the cellular tissue The patient's health has been perfect since the operation

Dr James B Chadwick, of Boston, referred to a case of extra uterine pregnancy which he treated with the constant current constantly interrupted This was continued three or four weeks before the symptoms ceased Five weeks later the fœtus protruded into the vagina and was removed

Dr. A Martin, of Berlin, had operated on sixteen cases of extra-uterine pregnancy The treatment by electricity has not met with much favor in Germany Tubal pregnancy is the most common form of this accident, and this can be easily diagnosed and easily operated on He had operated on nine cases of tubal pregnancy and all but one have recovered In this case the tube had burst and the abdomen was filled with blood before the operation was done Death resulted from the hæmorrhage The treatment of the other forms of extra uterine pregnancy will depend upon the symptoms and the course In these cases the chief objection is the danger of hæmorrhage from the placenta, but he had experienced no difficulty in dealing with the placenta

Dr Matthew D Mann said the electrical treatment of these cases has advantages over all other methods of treatment The dangers connected with the use of electricity where puncture is not made, are very slight If this method fails we can still perform laparotomy

Dr. Apostoli, of Paris, said that where a case of extra uterine pregnancy has been diagnosed in its earliest stages, the use of electricity should be tried before resorting to any operative procedure The faradic current is not to be depended on He had accidentally used the faradic current on the womb in cases of pregnancy, not knowing that the condition was present, and no abortion has resulted On the other hand, he had accidentally used the galvanic current under these circumstances, and abortion has been induced He recommended the introduction of one electrode into the sac, while the other is applied externally, and in this way if a strong current is used the death of the fœtus is assured at one sitting

Dr Janvrin, of New York, reported a case of extra uterine pregnancy in which galvanism was employed The patient died from bursting of the tube after the third application He had become convinced that the condition of collapse and colicky pain observed in cases of tubal pregnancy is not due to distension of the sac, but to the rupture of small vessels in the peritoneal covering of the tube The treatment of these cases is not galvanism, but as soon as we have made our diagnosis we should, on the first evidence of shock or colicky pains, at once remove the tube by laparotomy and thus give the patient a chance of being a well woman

Dr Van De Warker said that it has been shown that the use of electricity is not dangerous, and if it fails we can resort to laparotomy If Dr Janvrin's view is right we should have hæmatocele, but in his case where there were repeated attacks of pain there was no evidence of hæmorrhage With reference to the recommendation of Dr Apostoli, he thought that the introduction of an electrode into the sac would be as dangerous as laparotomy

Afternoon Session

Dr Frank P Foster, of New York, read a paper on

Vaginal Injections in Sims' Posture

The value of large vaginal injections of hot water in the treatment of inflammatory conditions of the pelvis is now recognized Even when the rules ordinarily laid down are faithfully carried out it is possible that the efficiency of this measure may be still further increased The main desiderata are the penetration of the water to a position closely contiguous to the seat of the disease, and its application in a quantity sufficient to secure the maximum action of the heat To fulfil these requirements the speaker had used the injections with the patient in the Sims' posture, or rather in a posture somewhat more prone than that of Sims With the woman in the dorsal position the quantity of water in the vagina at one time is decidedly smaller than that which is required to fill the canal when it is distended by atmospheric pressure, as occurs when opening the introitus with the patient in Sims' posture It seems reasonable to suppose that the effect of a large quantity of water in the vagina will be greater than that of a small quantity When the injection is concluded this large quantity of water can be retained for some time The greatest advantage is, however, the gravitation of the abdominal contents towards the diaphragm, thus bringing the hot water in closer relation with the diseased parts With the ordinary appliances there is some objection to this procedure,

but with the vaginal douche described some years ago by the author, no difficulty is experienced

DR CHARLES JEWETT, of Brooklyn read

A NOTE ON THE TREATMENT OF PUERPERAL ECLAMPSIA,

in which he called attention to the value of veratrum viride in this class of cases Its use in convulsive affections has been known for many years, but has not been generally recognized Veratrum viride, if a reliable preparation be employed, is a safe, prompt and efficient remedy in convulsions Its value in eclampsia seems to depend on its effect on the vasomotor tonus Used with proper precautions veratrum viride is perfectly safe A careful search of the literature reveals no death due to its use in the treatment of convulsions It is important that the patient should be kept in the recumbent position while taking the drug The fluid extract of the rhizome is the best preparation Hypodermic injection of the drug is the only reliable way of bringing the circulation promptly under its influence The average dose is 10–20 ♏ The smaller dose repeated in half an hour will usually suffice The guide to the use of the drug is the frequency of the pulse Experience has shown that no convulsion will occur if the system is sufficiently under the influence of the drug to hold the pulse under sixty per minute The average time required to develop the effect of a single dose of the drug is half an hour The average quantity given does not exceed twenty to thirty minims in all Twenty two cases were reported in which this treatment had been employed Of this number six died, three by complication and three from the eclampsia In the fatal cases from twenty-four to thirty convulsions had occurred before the treatment was begun In most cases other remedies, such as chloroform and hydragogues, were employed, in addition to the veratrum viride The most unpleasant effect noticed has been nausea and depression, but these were only transient

OFFICERS FOR THE ENSUING YEAR

President—Dr Robert Battey, of Rome, Ga

Vice Presidents—Dr Jas R Chadwick, of Boston, and Dr A Reeves Jackson, of Chicago

Secretary—Dr Joseph Taber Johnson, of Washington

Treasurer—Dr Matthew D Mann, of Buffalo

Council—Drs Frank P Foster, New York, C D Palmer, Cincinnati, Jas B Hunter, New York, and R Stansbury Sutton, Pittsburg

The following new members were elected Drs Howard A Kelly, Philadelphia, Cornelius Kollock, South Carolina, Bache McE Emmet, New York, and H T Hanks, New York

The report of the committee of conference with reference to the formation of a *Congress of American Physicians and Surgeons*, was received, but the recommendations of the joint committee were *not* adopted

The Society then adjourned to meet in Boston on the Third Tuesday of September, 1888

PHILADELPHIA COUNTY MEDICAL SOCIETY

Special Meeting, September 19, 1887

THE PRESIDENT, J SOLIS-COHEN, M D, IN THE CHAIR

MR LENNOX BROWNE, F R C S, of London, read a paper on

AN UNRECOGNIZED CAUSE OF MANY THROAT AILMENTS

In accepting the very flattering invitation of your President to speak a few words to the members of the Philadelphia County Medical Society, it appeared to me both more becoming and more profitable to offer you some practical remarks explaining the *rationale* of some of the commoner of throat ailments, than to attempt to magnify the office of the laryngoscope by the relation of rare and wonderful cases I was the more inclined to this view because I was well aware that, through the assiduous industry and well-known skill of your President and other members of your Society, you have for some years been kept thoroughly posted in all that is new in laryngology It is now some ten years since first I sought an objective explanation of the condition known as *globus hystericus*, and since I commenced to make a systematic examination with the laryngoscope of every patient who came to me with this symptom The result was communicated in a paper to the Congress of Laryngologists held at Milan in 1880 I found that but very few cases, indeed, are of a hysterical character—that is, of the nature of a phantom sensation—though uterine or ovarian disorder is a not infrequent predisponent, or, at least, concomitant of the throat condition in the female sex

Extending the term *globus hystericus*, I find that, with hardly an exception, all and every other subjective sensation in the throat is symptomatic of an objective cause The chief of such feelings are those of a heat, a prickling, a swelling, a weight, a straw, a hair, or other foreign body A few patients —one especially, a hale farmer—have complained of a feeling of intense cold, which is sometimes relieved, sometimes aggravated, after food taking In some instances there is actual pain with spasm, cramp, and a sensation of choking, and not infrequently there is cough, this symptom varies in degree from a slight hacking, to the loud hyena like bark known as nervous laryngeal cough Many of the cases of the so called laryngeal vertigo, or as I prefer to call it, of laryngeal epileptiform seizures, are capable of explanation and cure, on the lines I am at present taking On examination of the throat of a patient with symptoms such as I have described, one may or may not see chronic congestion and relaxation of the fauces and uvula, enlargement of the tonsils or obstruction by caseated material of the orifices of the crypts, granular pharyngitis, or even laryngeal hyperæmia Where any one of these conditions is present, treatment thereof may or may not give relief, but none of them represents the class to which I would draw your attention, namely, that in which there is no generally recognized morbid state of local significance

The results of laryngoscopic investigations in my hands have shown that there is

1 A varicose, and even truly hæmorrhoidal, condition of the veins at the base of the dorsum of the tongue, sometimes at the under surface and sides, in which last case it may be symptomatic of mitral insufficiency, or of severe hepatic derangement, or even of cerebral lesion There is often a similar varicose state of the vessels in the superior surface of the epiglottis

2 An enlargement of the circumvallate papillæ at the back of the tongue, causing the epiglottis to be hindered in its movements—imprisoned, as your President first called it

Just drawing attention to the fact that the structure of these glands is very similar to that of the tonsils, I may mention that in a few instances I have seen actual blocking of the orifices, similar to the condition known generally as chronic follicular tonsilitis

I may also note that it is not possible to see these things either with a tongue depressor or in the laryngeal mirror as ordinarily employed Many observers, especially beginners, seem to consider that their sole aim is to see the vocal cords, and, if these are sound, they write down, "larynx normal," but they omit to look well to the frame work To see this condition of lingual varix and glandular hypertrophy, the mirror must be placed quite high up in the throat

Where, as is often the case, there is no actual or noticeable enlargement of the thyroid gland, it will be observed, on passing the hand gently over the front of the throat, that there is a distinct fulness of the thyroid isthmus If the least pressure be made at this situation, the patient—not necessarily a female—will complain that the abnormal sensation is at once excited, and, on being questioned, will admit that when it occurs the collar is felt to be too tight for the neck

Inquiring into the general health, and happily failing to find any of the more serious lesions to which I have alluded, it will be noted that habitual constipation and a general defective circulation are both frequent symptoms, while in others there will be concomitant evidences of a varicose diathesis, as rectal hæmorrhoids, varicocele, or varicose veins of the extremities

In females the menstrual flow is often morbidly frequent or excessive, and there are other evidences of an enfeebled vasomotor control Abuse of alcohol and tobacco are excitants of the condition, and in the cases of singers or public speakers, defective methods of filling the lungs—forcing the lower registers upward, or other functional fault which may lead to undue strain on the palato pharyngeal muscles and engorgement of the vessels in this region—are fruitful predisponents

In this connection, I may refer to the accurate explanation offered by your fellow citizen, Dr Carl Seiler, of the etiology and pathology of chronic pharyngitis when occurring to voice users

Some of those obscure cases which come under our occasional notice, of the presence of small quantities of blood in the mouth, or of the taste thereof on rising from sleep, will be explained by the leakage of one or other of these enlarged and hæmorrhoidal venous capillaries in the region now under consideration

A few words as to treatment If the case is not of long standing or of aggravated character, correction of the main constitutional cause—cessation of the faulty method of voice production, or prohibition of a vicious habit or indulgence—may be sufficient to effect a cure, but this is rarely the case Of remedies, I give chalybeates and aperients with digitalis or ergot, as may be indicated Locally, astringent applications, especially of chloride of zinc or perchloride of iron, are by no means without avail, they can be applied by the patient himself Gargles as ordinarily employed are useless, and occasionally are productive of exacerbation of the symptoms Not so if employed by the method known as that of von Troeltsch Of lozenges, I find those of muriate of ammonia much more active in leading to resolution of the venous congestion, than those of red gum, rhatany, etc

Recent investigations show that the astringent properties of tannin have been exaggerated Where the uvula is relaxed, the snipping of an elongated portion, especially if other functional or constitutional faults are corrected, may lead to a cure, but in a certain proportion of patients in which the promises of the specialist as to the good effects to be gained by the procedure are not realized, the cause of failure will be found in non recognition of the various vessels Treatment of these is best effected by the galvano cautery point, and it is necessary to seal each individual enlarged vessel For this purpose it may be necessary to make more than one application Lastly, there is often a hyperæmic tumefaction of the vessels, glandules, and submucous tissues of the pharynx, naso pharynx, and turbinated bodies, these will also be best treated by galvano cautery

In conclusion, I would say, that in case it may be objected that the conditions I have described are but representative of an advanced chronic congestion, I do not deny that such occasionally may be the case In the majority, however, *there are no* such antecedents, and where the two exist, the practitioner will fail to cure his pharyngitis, or what not, until he has recognized and treated the varix

Dr Carl Sieler said I quite agree with the speaker, that the *globus hystericus* is rarely of purely imaginary origin Some chronic inflammation of the upper part of the upper air passages usually accompanies this distressing condition As he truly says, pharyngitis is *one of the most* common causes of this symptom At the same time the pharyngitis is to my mind, as a rule, *the consequence of* remote causes which may be looked for in one of three different directions—in a disturbance of the gastric system, in a disturbance of the respiratory function of the nose and naso pharynx, and, finally, and most commonly in public speakers and singers, in a faulty use of the organ of the voice This latter condition is frequently met with in those who simply

use the voice for ordinary conversation The constant irritation thus produced leads to hyperæmia and chronic inflammation, which extends upward, rather than downward, into the trachea In the treatment of the condition described, I think that little can be accomplished by the application of remedies to the apparent seat of the disease, but that the cause must be looked for and removed

CHICAGO MEDICAL SOCIETY

Stated Meeting, September 5, 1887

THE PRESIDENT, WM T BELFIELD, M D, IN THE CHAIR

DR CHARLES W PURDY read a paper entitled

THE SPECIFIC GRAVITY OF THE URINE, AND ITS RELATIONS TO STRUCTURAL DISEASES OF THE KIDNEYS

(See THE JOURNAL of Sept 10, p 325)

DR J J M ANGEAR I think the point that has been brought out with reference to the apparent and real specific gravity, is of great value, but there is some question in my mind as to the propriety of the use of these terms, going back of that it might be necessary for us to know what the urine is If the urine consists of all the water that passes out of the body, whether it passes through the kidneys and finally through the urethra, or whether it passes out through the skin or into the alimentery canal and then passes out, I can readily see the propriety of the use of the term apparent and real specific gravity, but I doubt if our present knowledge of pathology would enable us to occupy so large a field If the urine is that watery excrement which passes through the kidneys and out through the urethra then I don't see that we can use the term apparent and real specific gravity because the specific gravity of the fluid the patient passes at any time is its real specific gravity The term may be covered better by expressing it as the solid matter contained in the urine, it would perhaps be less objectionable and would not be so likely to lead some of the junior members of the profession astray as the term real and apparent specific gravity I am sorry that the writer did not bring out a little more the nerve influence upon the function of the kidneys I think we may have a nervous condition where the specific gravity may be increased or diminished, we may have albumin in the urine as the result of a nervous condition We have noticed it more particularly perhaps in what is called hysterical patients, and in all cases of nervous excitement I think you will find the specific gravity of the urine diminished in all young people who are first called upon to appear in public, whether it be the child in school reading a composition or declaiming, or the young politician attempting his first speech, or the teacher in a medical college with his lecture, these mental conditions have a decided influence upon the specific gravity of the urine (the apparent specific of Dr Purdy would call it) because there is an increased amount of water, but that water may under other circumstances, as in cases of fever, or great mental excitement, or some nervous disease, pass out through the skin as perspiration, but that very water would pass through the kidneys if that condition did not exist So I think it would be well for us to take into consideration the propriety of the use of these terms and at the same time we must not forget the physiology of the nervous system and the function of the kidney

DR W F COLEMAN There is a question I would like to ask It is somewhat unsatisfactory to take the specific gravity with the urinometer, in fact, I believe the only perfectly accurate way of taking specific gravity is to take it by weight of volume I want to ask if Dr Purdy considers the urinometer sufficiently accurate for all practical purposes? There is a condition of the urine that we find occasionally —it contains a large quantity of fat Does that indicate renal organic disease, or is it likely to induce it? How does it usually affect the specific gravity?

DR H N MOYER said he was greatly interested in Dr Purdy's paper, as it was upon a subject to which he had paid special attention for some time The author lays great stress on the specific gravity of the whole quantity of urine passed during twenty four hours, *i e*, the total solids excreted by the kidneys, as an indication of the greatest diagnostic value, in estimating the degree to which the structural integrity of the kidneys may be involved He thought he had not overstated the importance of the sign, when he regarded it of more consequence than any other symptom of kidney disease A case had come under Dr Moyer's observation suffering from spinal concussion, it appeared to be a simple case and one unusually clear in its symptoms and history The case was to become the subject of a medico legal inquiry, and the urine was examined as a matter of routine It was found to contain one sixth by volume of albumin and gave a slight reaction for hæmoglobin The possibility of beginning Bright's disease, the symptoms of which had been mistaken for spinal concussion, was apparent An examination into the quantity of solids daily excreted showed them to be about normal On this single indication the diagnosis of spinal concussion was affirmed, and the subsequent history of the case confirmed the conclusion A point of practical importance is the difficulty patients have in collecting the urine, and the necessity of measuring it by the physician I have in my office several wide "salt mouth" glass stoppered bottles of a capacity to contain the entire urine for twenty-four hours They are graduated in ounces, (a paper scale attached to the side of the bottle answers every purpose) The patient passes the urine directly into this bottle, and the quantity is noted, a portion of the urine may then be sent to a physician for estimation of the total solids, or further examination

The coefficient mentioned by Dr Purdy, of 2 33 is a good one but it necessitates estimating the quantity of urine in cubic centimeters, and the use of a four-part equation The matter has been simplified by Prof Haines, who recommends as an equivalent the

multiplying the last two figures of a specific gravity expressed in four figures by 1 1 the result to be multiplied by the whole number of ounces to obtain the total solids expressed in grains This formula I have found sufficiently accurate in practice

Dr C W Purdy, in closing the discussion said In reply to Dr Coleman's question about the method of taking the specific gravity, I did not go into that simply because it is thoroughly treated of in several recent works, especially Hoffman and Tyson The most perfect way is undoubtedly by the balance, the actual weight The best apparatus made in this country is made by Squibb If you use a urinometer you will find that they vary very much, they may start off at the standard temperature of 60° F all right, but they seem to go largely by guess after you get up 5 or 10 degrees There is a very fair instrument made with thermometer attachment There is one matter of very great importance if you examine urine freshly passed, as it is usually several degrees higher in temperature than normal Every 7 degrees rise in temperature will require 1 degree to be added to the specific gravity of the urine, consequently you will have about 5 degrees to add to urine of a temperature of 95° degrees which is about the temperature when passed If the kidneys are sound they will throw out water and solids in proportion to the man's weight, if diseased they cannot do it They may do more rapid functional action for a time but they will fall below normal, if the kidneys are essentially diseased the specific gravity must come below the normal There is another point which is very valuable and which surgeons should take notice of It is important to observe the specific gravity of the urine before every surgical operation I think when the specific gravity of the urine is materially below normal it is dangerous to operate in the majority of cases, it may be very dangerous, especially if the urine is deficient in chlorides I did not go into the elements of the urine excreted, dealing with urea, etc , that would make the question very complicated I wished to make it simple and easily understood as it is a question inclined to be overlooked by the majority of observers

Dr Moyer I would like to know if Dr Purdy does not think that the specific gravity can be estimated accurately enough for chemical purposes, by the ordinary urinometer, corrected by the Yale Observatory, if allowance is made for the variation in temperature

Dr Purdy I think it can be

FOREIGN CORRESPONDENCE

LETTER FROM LONDON

[From our own correspondent]

Diphenylamine a Test for Watered Milk—The Red Cross Conference—Hereditary Ichthyosis—The Cause of Morning Sickness in Pregnancy—Amylene Hydrate, the new Hypnotic—Iodide of Potassium Treatment of Consumption—Dr Ferrier

A new and curious test has been discovered by which the smallest addition of water to milk can be detected It is based upon the fact that all well and river waters contain an appreciable amount of nitrates They are either nitrates of soda, of potash, of ammonia or of lime, according to the source from which the water is drawn, and when the liquid is evaporated carefully to dryness, the presence of these nitrates can easily be detected in the residue But there is a means of detecting them without the trouble of evaporating the liquid down to dryness It has lately been found that drinking water containing nitrates yields a blue color when a little sulphate of diphenylamine is added to it This is the new test In order to carry it out a certain quantity of the milk to be examined is placed in a new porcelain capsule, and a few drops of the new reagent added The best way of making the experiment is to place first in the porcelain dish about 20 drops of the sulphate of diphenylamine, and then add the same quantity of milk to it, if the latter contain only 5 per cent of well water of the average quality, a blue line will gradually appear A solution of sulphate of diphenylamine should be placed at the disposal of every householder, with instructions for use printed on the label Armed with this and a common lactoscope, the smallest water adulteration would be easy of detection

At the sitting of the Red Cross Conference which was attended by the Emperor of Brazil, a resolution was adopted requesting the States and Associations which have adhered to the Geneva Convention to carry out the antiseptic treatment of the wounded as soon as they have been removed from the line of battle It was further decided to thank the various Governments and railway companies for the gratuitous transport of provisions for the benefit of the wounded, and to express a wish for the generalization of those facilities

Dr Date has drawn attention to an interesting case of hereditary ichthyosis occurring in a man aged 31, who had the disease well marked on the soles of both feet and the palms of both hands The family history showed that his great grandmother on his father's side was the first member of the family known to be similarly affected Next came her daughters, then the patient's father and uncle The children of the foregoing mostly suffered in the same manner The hands and feet appear natural at birth, the disease appearing about two or three weeks later, in every case being strictly confined to the soles and palms of the hands

Dr Oliver, of the Hospital for Women, considers that the cause of morning sickness during pregnancy may be due to the nerve centre which regulates the process of assimilation being either in apposition or at least in direct communication with that which presides over the organs of generation Considering the close relationship that exists throughout life between the two processes of assimilation and reproduction, there can be no doubt that the representative nerve centres act and react upon each other When, consequently, the uterus becomes the nidus for a developing germinal mass, the molecular disturbances radiated therefrom to the reproductive centre are liable to be transmitted to the pneumo-

gastric as well, and induce either a feeling of nausea or actual emesis Usually, however, in the course of a few months, through habit, the pneumogastric centre becomes tolerant and the symptom evidencing disturbance at the same time disappears Dr Oliver can only suggest that the change from the recumbent to the erect position during sleep renders the whole nervous system more liable to explosive disturbances, as being the reason why the sickness is more especially experienced in the morning

A new hypnotic called amylene hydrate has recently been rather extensively experimented with For a man the dose is 3 to 4 grams to secure a sound, calm, refreshing sleep of six to nine hours' duration The hypnotic action of amylene hydrate is not so energetic as that of chloral hydrate, but stronger than that of paraldehyde But it affects the heart much less than chloral hydrate does, and it is superior to paraldehyde, inasmuch as it can be given in smaller doses, is easier to administer, and does not impart to the patient's exhalations the disagreeable odor that is remarked when paraldehyde is given It is stated that as a hypnotic 1 gram of chloral hydrate is as energetic as 2 grams of amylene hydrate But having less action on the heart, the attention of practitioners will at once be drawn to the new hypnotic Neither does it appear to produce congestion, and not interfering with the action of the bowels, can be administered in diseases of the digestive organs It can also be given as enemata when necessary

Dr Weaver claims to have carried out and gradually improved a successful treatment of pulmonary consumption for a quarter of a century The doctor holds that iodide of potassium produces a condition of blood in which micro-organisms, including the tubercle bacillus, cannot live, but no evidence is adduced in his new "Practical Treatise on the Cure of Pulmonary Consumption" to prove that its presence is incompatible with bacillus life, and if, as he suggests in one part of his book, the function of these microbes may be that of scavengers to get rid of effete and exhausted matters, it is difficult to explain why he attempts interference with such useful parasites

The Balz Medal of the Royal College of Physicians has been awarded to Dr David Ferrier

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

Resorcin in Pertussis—Cerebral Irritation in Children—Preputial Dilatation as a Substitute for Circumcision—Ignipuncture of the Tonsils—Dermic Cyst of the Scrotum

The first meeting of the New York County Medical Association after the summer vacation was held the third week in October, when Dr J Lewis Smith, President of the Section of Diseases of Children of the Ninth International Medical Congress, gave a review of some of the more important papers which had been presented to that Section of the Congress These were four in number, one by Moncorvo, of Brazil, one by Jules Simon, of Paris, and two by St Germain, of Paris

The first was on "Pertussis and its Treatment with Resorcin," in which Moncorvo, whom Dr Smith regards as the ablest living authority on whooping cough, gave an interesting account of the microscopical researches which confirmed his belief in the bacterial origin of this disease This being demonstrated to his satisfaction, he selected resorcin as the best available remedy for local application, on account of its antiseptic power, its solubility and its lack of acidity Since 1885 he has been using cocaine as a preliminary to the resorcin, as he found that it lessened the intensity and frequency of the cough before the resorcin had had time to destroy the morbific germs He uses a 10 per cent solution of the cocaine and an 8 per cent solution of the resorcin, and this combination he believes constitutes the best treatment for whooping cough now at our command

The paper by Jules Simon was on "Cerebral Irritation in Infants and Young Children" Although many of these cases are no doubt due to such hereditary influences as alcoholism, insanity and syphilis, a considerable number were, he said, undoubtedly attributable to the deplorable mismanagement of children at the breast so often met with In the treatment of the condition it was necessary that a special and strict hygiene should be enforced, and all sources of excitement carefully eliminated The child should be kept constantly in the air and removed to the country (preferably the sea shore) if possible As to medicinal measures, the bromide of potassium with laxatives as required were all that was necessary, as a rule, the bromide being suspended from time to time for intervals of three days

Dr Smith said that the matter referred to was, in his opinion, one of great importance, and also one which had not as yet received as much attention as it deserved Infants such as were described in the paper were frequently met with in American households, and the symptoms noted were apt to be attributed by the friends to dentition or intestinal worms The causes of the cerebral irritation, however, were now looked for elsewhere by the more intelligent class of physicians, and it was fully recognized that the gum lancet or the use of vermifuges would only do harm There could be no doubt that, in addition to hereditary influences, the treatment the infant received had much to do with this nervous excitability, and that the habits of modern society interfered to no small extent with a well regulated management of the nursery While there are no structural lesions at first in this condition, parents ought to be impressed with the fact that it was liable to result in grave diseases, such as sclerosis or meningitis In such cases, like Simon, he uses both hygienic treatment and the bromide of potassium

The first of St Germain's papers was on "Preputial Dilatation as a Substitute for Circumcision" As the latter was sometimes followed by serious ac

cidents, it was desirable, he thought, that dilatation should be used in its stead in all cases in which this proceeding was practicable An examination of the statistics of the subject showed that dilatation was impracticable in only about one in every 300 cases The dilator he employs is like that of Nélaton, except that it has two blades, instead of three Gradual and slow dilatation of the preputial orifice is practiced, and afterwards daily movement of the prepuce, alternately covering and uncovering the gland

The other paper by St Germain was on "Ignipuncture of the Tonsils," which he believes is destined one day to supersede tonsillotomy It is, he said, a perfectly safe procedure, and therefore much preferable to the latter By the aid of a Smith's gag a thermo cautery is introduced into the mouth and inserted into the tonsil to the depth of 1 centimetre The operation is repeated every eight days, and from two to four sittings are required, at the end of which time the tonsil is found to be almost completely shrivelled up It has proved very successful in St Germain's hands, and although he has employed it now in a large number of cases no bad results have been noted from it

Dr Smith said that he had applied to Dr A D Rockwell, the eminent electro therapeutist, for an expression of opinion in regard to the advantage and practicability of this procedure, and Dr Rockwell had written that, although the author's description of the method was too brief and vague to enable one to judge definitely of its merits, the matter seemed plausible and worthy of attention While the galva no cautery had the advantage over the knife of giving rise to much less danger of hæmorrhage or pyæmia, its application was too painful and required too long a time (six or eight minutes at a sitting), to be successfully resorted to in the case of young children Ignipuncture, on the contrary, could no doubt be employed with facility, because its action was instantaneous

In the discussion which followed Dr Smith's address Dr C A Leale suggested the use of bromide of sodium in the place of bromide of potassium in the cerebral irritation of children, as he had found that the former was much less apt to disagree with the stomach than the latter As to dilatation of the prepuce, this had long been successfully practiced in America, and St Germain's paper therefore contained nothing that was known here

Dr J R McGregor said that in regard to whooping cough he believed that in addition to the primary cause, there was an intense neurosis present, which it was necessary to control in order to deal satisfactorily with the disease Almost every physician had some favorite remedy, and personally he had obtained the best results with oxalate of serium, which he gave in 5 grain doses once a day, in exceptional cases repeating the dose at night He could see no great objection to circumcision, and believed that many of the cases in which diphtheria followed it this was due to carelessness on the part of the operator in regard to instruments, etc

Dr J W S Gouley said that when the preputial orifice was very narrow it was not safe to attempt retraction, on account of the danger of producing paraphimosis, which was always a serious matter in children In such cases there was no question in his mind that, as a rule, excision of the prepuce constituted the last treatment Dilatation, or, more properly, divulsion, was not an easy operation by any means, and the younger the child was the more difficult it was to perform It could be most satisfactorily accomplished by means of Trousseau's tracheotomy dilator, but the procedure was always to be condemned when the prepuce was narrow and indurated

At the close of the discussion Dr Alfred L Carroll read a paper entitled "Mineral Water Miracles," in which he gave a forcible exposition, abounding in lively satire, of the ridiculous claims of some of the mineral waters now in vogue, after which Dr Gouley presented a dermic cyst of the scrotum (the removal of which had also necessitated that of one of the testicles), in which fatty degeneration had been followed by calcareous infiltration, accompanied with the development of a small amount of osseous tissue, the bone cells being found present under the microscope P H P

CYSTOCOLPOCELE COMPLICATING LABOR

Dear Sir —In THE JOURNAL of October 15, page 502, appears the report of a case of labor complicated by cystocolpocele, in which the author says he has found but 37 recorded cases If of value to the profession, allow me to report the following case

On September 24, 1887, I was called to attend a case of labor at full term Labor pains had occurred regularly for the past six hours, though light in character Upon making a vaginal examination, I found a fluctuating tumor about the size of a fœtal head, depending direct from the superior vaginal wall, the tip of the finger could detect the patulous os, but could not reach the presenting part of the child The tumor was not painful, nor had there been marked desire to urinate Patient had passed water several times that day

I suspected a prolapsed bladder, and requested the patient to urinate, and then found that the obstruction had disappeared, with the exception of the shrunken walls, which lay in rugæ on the upper surface of the vagina No other trouble was experienced, and in about two hours she was delivered of a fine pair of twins

This was her fourth accouchement, and in the three preceding ones she had been attended by a midwife, never knew of the prolapse, and had experienced no trouble from it

Respectfully,

A J C SAUNIER, M D

Libertyville, Ill , Oct 20, 1887

GLEDITSCHINE-STENOCARPINE

Dear Sir —The fact, seemingly well proven by the experience of Drs Seward, Claiborne, Knapp, Jackson, Mitchell and others, that the newly discovered alkaloid, gleditschine stenocarpine, is largely

like cocaine in its power as a local anæsthetic, has prompted me to determine whether it has a value akin to that drug, as a stimulant in the treatment of opium habitués, and I am now experimenting in this direction, using a 2 per cent solution exclusively by subcutaneous injection That cocaine, hypodermically, is a valued aid in treating the opium neurosis is beyond question, in my opinion, but it is not a specific, and should never be used for this purpose by the patient himself, be he physician or layman Should gleditschine have a similar value, it may be found free from the ensnaring danger of cocaine, though, assuming its stimulant power, this freedom from risk will not be likely, and we shall note, probably, in the not far future, baneful effects from its abuse, and gleditschine inebriety be added to the list of toxic neuroses

It has been stated by Dr Seward that he "has observed antidotal effects to gleditschine from morphia," and Mitchell (W H) asserts "it is a direct antagonist of morphine and opium, 10 drops of the 2 per cent solution neutralizing 1 grain of morphine or 6 of opium " Experiments on rabbits now being made by myself will, it is to be hoped, sustain these claims "

The 2 per cent solution can be obtained of Messrs Lehn and Fink, New York City, at a present wholesale cost of $6 an ounce I shall be pleased to receive and report the experience which any reader of THE JOURNAL may have on this subject Yours very truly, J B MATTISON

314 State St , Brooklyn, October 15, 1887

BOOK REVIEWS.

THE PHYSICIAN'S VISITING LIST (Lindsay & Blakiston's), Thirty seventh year 1851–1888, with many improvements Philadelphia P Blakiston, Son & Co

This visiting list is so well known that no description is needed Of the various visiting lists it is one of the lightest, strongest, least cumbersome, and most convenient

SURGERY, ITS THEORY AND PRACTICE By WILLIAM JOHNSON WALSHAM, F R C S , Assistant Surgeon to St Bartholomew's Hospital, Surgeon to the Metropolitan Free Hospital, London, etc With 236 illustrations 8vo , pp ix–655 Philadelphia P Blakiston, Son & Co 1887 Chicago W T Keener

While in no sense a "short cut to surgery" Mr Walsham's book seems to be in the main intended as a manual or handbook for the student and practitioner of surgery The subjects with which every student ought to be thoroughly acquainted are given special prominence, while the rarer forms of injury and disease have either received but short notice or have been entirely omitted The details of operative surgery and minor surgery and bandaging, with such other things as the student is supposed to be taught practically in the wards, are but briefly discussed

The first two sections, occupying 119 pages, are devoted to "General Pathology of Surgical Diseases," and "General Pathology of Injuries," for the introduction of which into a manual the author is to be commended The illustrations, as a rule, are good, in that they show what they are intended to represent Many of them are new, and we note with pleasure the conspicuous paucity of many too familiar old ones The book is a good one, and written in Mr Walsham's well known lucid style

MISCELLANEOUS.

COMMEMORATIVE MEDAL, NINTH INTERNATIONAL MEDICAL CONGRESS —We learn that a contract has been made with a first class medalist connected with the United States Mint at Philadelphia, to engrave and stamp the commemorative medal for the subscribing members of the Ninth International Medical Congress The work is to be executed in the best possible manner As several months will be required to prepare the dies, members of the Congress who have not subscribed, we presume can still do so on application to Dr J M Toner, 615 Louisiana Ave , Washington, D C , who has the matter in charge

TYPHOID FEVER IN CINCINNATI —Telegraphic dispatches from Cincinnati state there are more than 500 cases of typhoid fever in the City, and that the outbreak of the disease is thought to be due to the condition of the Ohio river, which is much lower than it has been for many years

FLORENCE NIGHTINGALE, the famous heroine of the Crimea, is reported dying at her home in London, from the effects of her perilous labors during the days in which she devoted her life to the care of soldiers wounded in battle

DR JAMES A GRAY, one of the editors of the *Atlantic Medical and Surgical Journal*, died on October 7, aged 37 years

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM OCTOBER 15, 1887, TO OCTOBER 21, 1887

Major W D Wolverton, Surgeon, detailed as member of Army Retiring Board at Washington, D C , convened by S O 78, A G O , April 5, 1887, vice Major C C Byrne, Surgeon, hereby relieved S O 241, A G O , October 15, 1887

Capt Edwin F Gardner, Asst Surgeon, relieved from duty at Ft Reno, Ind Ter , and ordered for duty at Ft Lewis, Col S O 241, A G O , October 15, 1887

Capt Jno J Cochran, Asst Surgeon, now on duty at the Presidio of San Francisco, Cal , is assigned to temporary duty at hdqrs Div of the Pacific, as assistant to the Medical Director of that division S O 244, A G O , October 19, 1887

First Lieut C B Ewing, Asst Surgeon, granted leave of absence for one month, on surgeon's certificate of disability S O 112, Dept Mo , October 18, 1887

Nathan S Jarvis, to be Asst Surgeon, U S Army, with the rank of First Lieut , October 14, 1887

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY, DURING THE WEEK ENDING OCTOBER 22, 1887

P A Surgeon H G Beyer, ordered to hold himself in readiness for orders to the "Trenton "

Asst Surgeon S S White, ordered to hold himself in readiness for orders to the "Trenton "

P A Surgeon F B Stephenson, detached from the "Bache," and ordered to the Navy Yard, Boston

Asst Surgeon E P Stone, detached from the "New Hampshire," and ordered to the 'Bache "

Surgeon T H Street, detached from the "Patterson" and placed on waiting orders

INJURIES OF THE ABDOMEN AND THEIR PROPER TREATMENT

Read in the Section on Surgery, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY N B CARSON, M D,

OF ST LOUIS, MO SURGEON TO THE MULLANPHY HOSPITAL, ETC

Sir Spencer Wells has said "abdominal surgery, though not without just claims to the credit of having done good service to humanity, must still be looked upon as a branch of our science and art which, still important, calls for continued search for truth, and for constant efforts to improve methods of practice from every surgical stand point"

To no branch of abdominal surgery does this statement apply with greater truth than to that pertaining to abdominal wounds No branch of this subject is receiving larger attention to day than is this, and in no other is there greater necessity, for in no department of the subject is there so much uncertainty The subject is being discussed at the meetings of surgical societies and in journals all over the world, and yet, notwithstanding all that has been said, there is still much to be learned, for the subject is only in its infancy, and although operative procedure in these cases meets with much opposition, it will nevertheless, and at no distant day, take its place with ovariotomy as an acknowledged operation

I do not expect in this paper to add anything new, or to make any suggestions which have not been already offered, but simply to give my experience and add my name to the list of those who have already spoken in favor of operating in these cases, instead of treating them as Dr Martin, of Herde, justly remarks by "opium euthanasia"

As to wounds of the abdominal walls, little need be said, as the various text books treat them so fully as to require no more than a passing notice on my part From personal experience I am in doubt as to the possibility of a force being applied to the abdominal wall with sufficient violence to produce an inflammation of the peritoneum, *per se*, without rupturing some of the viscera

If, however, peritonitis should follow such an injury, I would, upon the first indication of inflammation, open the abdomen and keep it thoroughly drained The success attending this plan of treatment in cases of peritonitis from other causes, I think, fully justifies the procedure

"The effect of contusions of the abdomen is not always limited to the walls, but extends sometimes to the whole visceral mass, but more commonly to the large solid and fixed viscera—the liver, spleen, and kidneys—and less frequently to the hollow viscera, the stomach, intestines and gall bladder Probably all of the organs contained in the abdomen, even the blood-vessels, may be torn or ruptured without the existence of external wounds" Otis reports Where the solid organs and blood-vessels are wounded by blows or falls on the abdominal walls without penetration, the injury is generally so great as to give the surgeon little chance for rendering aid, the patient rarely recovering from the shock Hæmorrhage is necessarily great and post mortems usually show the cavity filled with blood If, however, the patient should survive the shock and the symptoms indicate surgical interference, I would open the abdomen, and if a bleeding vessel were found, would ligate it, or if the liver were ruptured would control the bleeding either with the thermocautery, or a solution of sub sulphate of iron, or pack it with aseptic gauze, bringing the free end out through the abdominal opening In case the spleen or either kidney were the organ involved, I would remove them This operation has been done with sufficient success for other causes than injury, to teach us its possibilities

As to the pancreas, Senn has said all that can be said in regard to wounds of that organ, and I will not refer to it hereafter in the consideration of the subject

Up to the present time there has not been a successful case recorded where laparotomy has been done for the relief of intestinal rupture without penetration The nearest approach to success was the case of J Croft, of St Thomas's Hospital, who opened the abdomen of a man, who had been injured twenty four hours before by his companions jumping upon him and rupturing the bowel Laparotomy was done shortly afterwards and the bowel fastened to the external opening The patient survived the first operation, but as he did not gain flesh, and on account of discharges irritating the skin in the neighborhood of the opening, Mr Croft attempted to close this by resecting and bringing together the divided ends A month had elapsed since the first operation, but on account of sufficient nourishment not being taken up by the system, the

patient could not withstand the shock of the second operation and died within a few hours

The uncertainty of diagnosis in these cases is the reason operation is delayed until it is made certain by the advent of peritonitis, and thus many valuable lives are sacrificed, as the following cases that have come under my own observation in the last few months will show

The first case was that of a hostler who had been kicked in the abdomen, two days before he was brought to the St Louis Mullanphy Hospital, where I saw him a few hours after his admission He was moribund and an operation was out of the question The post-mortem showed the ileum ruptured low down, the peritoneum inflamed, the result of fæcal extravasation The patient, I feel sure, could have been relieved by an operation, as might also have been the following case—in which I assisted Dr Gregory—had the operation been done earlier The patient had fallen about four feet and struck the abdomen across the top round of a ladder There was considerable shock after the fall, with much pain which steadily increased instead of diminishing His condition went on from bad to worse until the following Tuesday at noon—three days after the injury—when the abdomen was opened, only as a forlorn hope A small rent in the intestine was discovered which was closed by the Lembert suture, and the cavity thoroughly cleansed, the abdominal opening closed, and the patient returned to bed, little if any worse for the operation, but he died six hours later

The symptoms in many of these cases are obscure, and when to operate will always be a question, while in others, as in the following, they are so clear that there cannot be any doubt In this case the patient was brought to the hospital where I saw him shortly after He was then collapsed—skin bathed in a cold perspiration, pulse low, vomiting everything taken into the stomach, abdomen much distended, liver dulness diminished, bladder empty, thirst intense Rupture of the bowel was diagnosed and laparotomy advised in case patient recovered from the shock, which he did not do Post-mortem showed ileum ruptured about its middle entirely across Neither the abdominal wall or peritoneum were injured, while the omentum immediately under the site of the injury was bruised, and in places contained extravasated blood

If called to see a case of non-perforating injury of the abdomen, if the symptoms indicated in any way an injury of the viscera, I would advise immediate operation, and unless I did so, would consider I had not done my duty, as we shall see from tables later on, that exploratory laparotomy is far less fatal than the expectant plan of treatment heretofore adopted in these cases

As the table of Sir W MacCormac is more complete than the one I had compiled, I will refer to it In these tables twelve cases are recorded, all of which were fatal

The same author has collected sixteen cases of laparotomy for intra peritoneal rupture of the urinary bladder of which six were successful, and ten failed These results are certainly encouraging, especially as these cases have been almost universally fatal before the *bold* and *daring* surgeon of the day undertook to save them Renigald Harrison—"International Ency of Surgery," Vol vi p 329—says "Where the rupture has extended into the peritoneal cavity, I cannot find any evidence to warrant the belief that life has ever been saved without the intervention of surgery In the few cases where recovery has taken place, it has been directly traceable to the aid which nature has received from the surgeon's hand"

The fatality of penetrating abdominal wounds is so generally recognized, that I almost feel like apologizing for referring to it It has been said that Mr Abernethy used quaintly to remark that "nature would have nothing to do with these cases, but stood by and shook her head, and left the patient to his hopeless fate" While nature stood appalled by the task before her, man, more daring and venturesome, was not willing to stand by and see his fellow man die without an effort to save him, and fortunately for mankind the introduction of antiseptics into surgery has enabled him to accomplish wonders, and the day is rapidly approaching, if not already here, when the man with a wound penetrating his belly has some chance of being saved

That the peritoneum may be penetrated with a certain degree of impunity without any very grave consequences, may readily be proved by a reference to the records of our hospitals, (provided the viscera are not injured), and by the few fatal results following exploratory laparotomy, which to-day is a recognized operation Still it is not a pleasant thing to open the abdomen, even if it is by enlarging an already existing wound, to find there was no cause for so doing

The question then arises What are the symptoms which should induce us to advise the operation? Certainly not simply because a body passed through the cavity, for there are many cases on record where different things have passed entirely through the belly without injuring, in the least, any of its contents The following case is in point, and as I believe it has never been reported will mention it An old miser, an inmate of the St Louis Mullanphy Hospital, having concluded he was of no use in this world, determined to get out of it He had in his possession an old dress sword, such as were worn in the good old times gone by, which he concluded to use in carrying out his purpose To make the killing sure, he entered into negotiations with a scissors grinder to have it sharpened But the grinder would not take less than fifteen cents, and the miser would not pay such an extravagant price, the bargain was not closed, and as a consequence the man did not get rid of himself The weapon was too dull to cut and passed entirely through the cavity without injury to its contents From this it will be seen that the question as to the viscera being wounded, is not always a matter of certainty, and the propriety of the operation becomes a question

The following interesting case was related to me by a gentleman in the country, for whose integrity I

A C L Ramsey, North west Lancet, 1885 iv, 1887	7 Male	Lapar, excision of gut	6 hours	Bad	Duodenum, contusion of colon	Died	

will vouch A woman had the abdomen divided entirely across There was no doctor in the neighborhood, and the relator's father-in law, a prominent man of the country, and whose advise was sought on all occasions, was sent for Realizing the necessity of doing something he invaginated the cut ends of the gut, returned it into the abdomen, and closed the external wound with an ordinary needle and flax thread (home made) As the relator expressed it, he got the right ends of the bowel into each other, and the patient recovered, living several years, to die of another trouble, not connected in any way with this injury From this case, if true, the possibilities of abdominal surgery can be seen

LAPAROTOMY FOR STAB WOUNDS

J G Brooks Medical Herald 1886 vol viii p 134	11 Male	Laparotomy and ligation of vessels	A few hours	Great shock	Abdominal wall and mesentery	Recovered	
Kwiecinski, Przegl lek Krakau 1885 xxiv 71	20 Male	Laparotomy and suture of wounds in intestines	1 hour	Fair	Small intestine	Recovered	
W O Roberts Kentucky Am. Practice 1884 xxix 13.	54 Male	Suture of wounds in intestine & mesentery enlargement of abd'l wound		Good	Small intestine and mesentery	Recovered	
J B Roberts Phila. Polyc., 1886 iii 93	19 Male	Laparotomy and suture of wound in bowel.	2 hours	Very bad	Small intestine	Died	Post m showed one wound in bowel overlooked
J B Deaver unpublished	Adult.	Excision of spleen		Great shock	Spleen	Died	Post mortem showed wound of kidney etc
Jobert, Günther Operationslehre.	23 Male	Enlargement of abdominal wound and suture of bowel			Small intestine	Died	

LAPAROTOMY FOR STAB-WOUNDS—CONTINUED

Operator and Reference	Age and Sex	Operation	Time of Operation after Injury	Condition at Time of Operation	Organs Involved	Result.	Remarks
T G Morton, unpublished	30 Male	Laparotomy, suture of omentum, ligature of bleeding omental artery	9 hours	Increasing pain about wound, emphysema, no shock	Wound of omentum	Recovered	
J B Roberts, unpublished	40 Male	Laparotomy, wounds all closed with Lembert's suture	45 minutes	Violent abd pain, free hæmorrhage	Small intestine, colon and mes	Recovered	
Davids, Günther, Operationslehre, Abtheilung IV, 163	Not given	Enlargement of abd'l wound, gut sutured			Small intestine	Recovered	Gored by ox Subsequently ventral hernia form'd in scar
Gal, Centralblatt f Chirurg, 1886, 686	45 Male	Enlarging abd'l wound	9 hours	Good	Abdominal wall	Recovered	Gored by a cow

The following interesting case occurred in my practice and is of especial interest, on account of its involving the medico-legal point, as to the propriety of operating in cases where the lives of two persons are involved instead of one As a matter of opinion, I think the interest of the second party should not be considered, as by his own act he forfeits all rights in that direction

I first saw this case—a woman about 40 years of age—thirty-two or three hours after she had been stabbed by her husband She was then somewhat under the influence of morphine Her condition, however, was good, the only indication of serious trouble was an occasional intermission of the pulse, which, however, was of good volume, etc The abdomen was painful on pressure and somewhat distended From the history of the case I learned that the patient had been accustomed to taking stimulants rather freely—that at the time of the injury there had been considerable shock, from which she had readily recovered I found upon examination, a knife wound three fourths of an inch in length, entering the cavity about an inch and a half below the margin of the ribs, and two inches to the right of the medium line It was supposed the knife had entered the transverse colon Laparotomy was advised and assented to by both herself and children As the surroundings were very unfavorable, I had her removed to the hospital, not very far distant, where, thirty-six hours after the receipt of the injury, I opened the abdomen, and instead of an intestine, I found the liver had been penetrated, and the further progress of the knife stopped by a stone which entirely filled the gall-bladder

The toilette of the peritoneum was carefully made and a drainage tube introduced at the lower angle of the wound Everything went on well until the evening of the third day when symptoms of iodoform poisoning set in, and she died on the morning of the fifth day The post-mortem examination showed the peritoneal cavity as nearly normal as possible, under the circumstances The left ventricle and arch of the aorta contained old well organized blood-clots The liver was perfectly healthy in appearance The post-mortem was not completed as the coroner did not think it necessary

I am at a loss to account for the bile that was found, as the stone certainly filled the gall bladder, and at the point of perforation was firmly adhered to the mucous membrane, nor were the bile ducts enlarged to indicate an engorgment of the liver I think, had the iodoform not been used the patient would have recovered

From all sources I have collected twenty eight cases wherein the abdomen has been opened for penetrating wounds Of these sixteen recovered, eleven died, and one, undecided, died on the third day Of this number eight involved the abdomen only, with five recovered, two deaths and one undecided Of the deaths one was evidently due to opium poisoning, of which the patient had been given 8 grains in a short time by the physician who saw him first In the other case peritonitis had already set in, and the patient was in a bad condition at the time of operation Of the remaining nineteen cases all had wounds involving one or more of the viscera Of this number ten recovered and nine died, a showing very decidedly in favor of laparotomy, as it is evident from the nature of the wounds and the parts involved, many, if not all, would have died had nature been left to care for them

The great mortality attending gun shot wounds can never be overcome, but I believe these cases need not remain as they have been in the past—beyond hope

Hunter McGuire places the mortality in this injury at more than nine out of ten The records of cases as far as I have been able to examine them verify this estimate I have not found a case of gun-shot wound involving the small intestines wherein death did not result When the stomach is the organ involved the patient has more chance of recovery, but such chances are so very few as compared with the unfortunate ones as hardly to be worth considering

In every case of gun-shot wounds of the intestines, says Park, where there was extravasation of the intestinal contents, death was the result, unless the

cavity was cleansed, and the opening of the abdomen is the only means we have to accomplish that end But how are we to decide when to open the abdomen, as the symptoms are not always plain in these cases, as the following that have come under my personal observation demonstrated

In the first case I saw—three hours after the injury—there were then no symptoms that would enable us to say that the abdomen had been penetrated As there was no shock, the pulse was regular and full—the abdomen nearly normal, and except the hole of entrance, showed nothing to indicate any serious injury underneath His expression was good and he complained of little or no pain (there had been no shock) As the surroundings were bad I had him removed a distance of three miles to the hospital Upon his arrival there, two hours later, his condition had changed little if at all A careful examination showed occasional loss of a beat in the pulse—a symptom I have almost invariably found when any of the important abdominal viscera are wounded—otherwise it was very good—voice strong, expression good, abdominal percussion showed slight increase in the resonance, except to the right of the umbilicus over a space about as broad as the hand where it was dull—almost flat The abdomen was opened six hours after the receipt of the injury, and the intestines found to have been perforated eight times—once at the mesenteric border Two and a half inches of the bowel had to be resected in one place on account of the laceration of the parts In the remaining perforations the edges were pared and the opening closed with Lembert sutures The cleansing of the cavity was not satisfactory on account of a portion of the intestine being adherent to the lower part of the abdomen, its great depth and the rigidity of the abdominal muscles The patient survived the operation three days, dying of septic peritonitis No post mortem was allowed

Another case, one which I saw in consultation with Dr Mudd, was one also which presented few symptoms to indicate that the abdomen had been entered and important viscera wounded

A young man, 17 years of age, accidently shot himself with a small target rifle, just above the umbilicus When I saw him with Dr Mudd, three days after the accident, there were really no bad symptoms, unless it was that the pulse, every little while, lost a beat The abdomen was tender but very little distended Laparotomy was advised and consented to by the father, who is one of our leading physicians

The reasons for advising the operation were the belief that the ball had penetrated some of the viscera, and that there were missing pieces of clothing, and also a beginning peritonitis

Upon opening into the cavity a wound in the liver was found, as was also the wound of entrance of the ball into the stomach, but not that of exit There were no evidences of extravasation The stomach wound had healed The trans colon was much distended, and showed symptoms of beginning inflammation, as did also the peritoneum generally

In this case the operation probably did harm instead of good, for I believe had the operation been left undone the patient's chances for recovery would have been better, although I have doubts as to the result being different

As to there being any symptoms or rules to guide us in our selection of cases for operation, I do not believe they exist in any definite form, and each case has to be decided upon its own merits I do, however, firmly believe that the day is not far distant when the great majority of these cases will reach the surgeon much sooner after the receipt of the injury, than they now do, and that a fair per cent of recoveries will be the result

From all sources I have collected forty four cases of gun shot wounds, for the relief of which laparotomy was done, with thirteen recoveries, thirty deaths and one doubtful This is certainly a favorable showing as compared with the let alone plan

Finally, I will refer to the excellent paper of F S Dennis and to his conclusions, as containing sound principles which should guide us in the selection of cases for operations

I wish to acknowledge my indebtedness to the tables of Sir W MacCormac for several cases not reported elsewhere

---

LAPAROTOMY AS A CURE FOR TUBERCULOSIS OF THE PERITONEUM

Read before the Section of Obstetrics and Gynecology, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY ELY VAN DE WARKER, M D

OF SYRACUSE N Y

SURGEON TO THE CENTRAL NEW YORK HOSPITAL FOR WOMEN FELLOW AMERICAN GYNÆCOLOGICAL SOCIETY FELLOW NEW YORK STATE MEDICAL ASSOCIATION ETC

The subject of this paper is well illustrated by the detail of the following case

Mrs C , æt 28 years, 4 years married, the mother of one child 1 year old, of medium size, light blonde, sought my advice for swelling of the abdomen, which she supposed to be a tumor She had noticed a gradually advancing enlargement for about two months On examination fluctuation was marked but diffuse, extending in an evident wave over the abdomen with the patient upon her back In this position the abdomen was flat and bulging on either flank, with protrusion of the umbilicus In this position, also, the area of percussion dulness corresponded to the extent of lateral fulness, while the umbilical region was clear, down nearly to the hypogastrium On changing her position to the side, the upper flank became clear on percussion, while the region of dulness was transferred to the lower side on a line nearly to the level of the umbilicus On reversing the position the regions of dulness and clearness changed sides The examination of the pelvic organs gave negative evidence The uterus approximated the normal in size and position, the organ was freely movable, and was not affected by abdominal manipulation except by the percussion wave, which could be felt in the vaginal cul de sacs The region of the liver was free from tenderness and

gave a normal outline on percussion The temperature was normal, the appetite fair, there was no cough, while the lungs offered no suspicion of disease She complained of indigestion and a tendency to looseness of the bowels with flatulency The urine was stated by the patient to be normal in amount The specific gravity was 1019, acid and free from albumen The patient was slightly falling off in flesh There was no œdema of the feet or eyelids

There was but one diagnosis to be made—that of ascites, but there was no evident cause of the peritoneal effusion She was placed upon tonics and diuretics and sent home She was seen at intervals of two or three months There was no change other than in a slow increase of the ascites and in the loss of weight In the early spring she had a troublesome cough which lasted five or six weeks, but abated by the use of simple remedies

Nothing further was seen of the patient until late in the fall of the same year A complete change was then observed in the condition of the abdomen The outline had lost the character of free fluid effusion, the flatness and bulging of the flanks had disappeared and the abdomen become prominent and rounded The area of percussion dulness had changed from the central region to the loins By deep palpation in the right iliac space an irregular hardened mass could be detected, and an induration of apparently the same size and character near the right hypochondriac region The wave of fluctuation was limited by the line of dulness at the epigastrium and at the flanks The uterus seemed free from any connection with the abdominal masses and was in a fairly normal position The umbilicus was yet protuberant

I was in great doubt as to the state of affairs The was no cough or hectic, the temperature was about normal, she had wasted considerably, the face was pinched and the expression such as seen with ovarian cystoma, not like that observed in malignant disease of the pelvic or abdominal organs The urine free from albumen The feet were slightly œdematous I abandoned the former diagnosis, but without offering a positive substitute, advised further delay

In March, 1886, respiration being difficult from pressure, and the abdomen painful, she was admitted to the Central New York Hospital for Women for the purpose of aspirating the abdominal fluid She was anxious for an operation, as she believed that she had a tumor, but I could not divest my mind of my first impression, and refused to operate in any other way than by aspiration We succeeded in removing only about a quart of straw-colored fluid, which did not materially reduce her size The fluid coagulated by boiling but not by standing, and the rather firm coagulum broke up into flocculent masses by excess of acetic acid It was not examined microscopically, which is to be regretted, as I believe important facts may be had by such an examination of the fluid in these cases

On June 10, 1886, she was again admitted to have her theory of the case acted upon, as I consented to operate I must confess that I had been gradually coming over to her view of the case, and now believed that the former ascites was masked by the subsequent development of an ovarian cyst I invited in Dr H D Didama to see her He gave her a careful examination, and while not positive, favored the operation of an ovarian cyst, and advised an exploratory incision

The next day I operated in the presence of Drs Didama, Totman, and the House Surgeon, Dr Adams I made an incision about 5 inches long, fully expecting to come upon a cyst, but on reaching the peritoneum no separation could be made between it and what what ought to correspond to a cyst wall, and yet what we regard as peritoneum was enormously thick I carefully worked my way through it and was rewarded by a jet of fluid from what appeared to be a cyst cavity The incision was enlarged to the full extent of the external wound, the patient turned upon her side and the cavity emptied Some further attempts were made to separate a cyst wall from the peritoneum, but it only resulted in tearing the peritoneum from the abdominal wall The idea of a cyst was abandoned and we confined our efforts to find out the nature of the case By inserting the hand a mass was brought into view which was so thickened and matted together that it was with difficulty recognized as intestine The peritoneum was rolled out and found to be studded with a great number of tubercles, from the size of a millet seed to that of a buck shot, some of them white, others yellow The intestines were everywhere beset with them The transverse colon, thickened and covered with tubercles, was adherent to the peritoneum from side to side, thus enclosing the cavity and giving to the fluid the appearance of being confined within the walls of the cyst

This ended the operation The cavity was carefully sponged out with warm corrosive sublimate solution (1–5,000), and the wound brought together, dressed with iodoform and dry absorbent cotton

The temperature never exceeded 100° and she made an exceedingly quick recovery Before the sutures were removed there was a great change in her appearance, her demand for food greatly increased, color returned to her cheeks, and before she left the hospital in three weeks had gained about ten pounds of flesh She went on gaining, and in three months was a strong, robust woman, and at this time, June, 1887, remains so None of the iodoform entered the abdominal cavity

If this were an exceptional case it would possess no merit worthy of record, but in the light of recent knowledge it must be regarded of value as a matter of accumulated experience Other cases of tuberculosis of the peritoneum and of the abdominal viscera appeared to undergo a remarkable amendment or apparent cure directly after the performance of laparotomy This has been observed sufficiently often to regard it as a possible sequence Why there is an arrest of progressive tuberculization after laparotomy it is difficult to say We know too little about the tubercular forces to begin with to predicate upon it any well defined explanation, in the

next place, there is total lack of precision in the method We may say that there is no operator of laparotomy for tuberculosis known to day, we simply know that it has happened in a discursive way, as a result of errors of diagnosis, as Hegar says Concerning laparotomy itself there is some confusion

At the first meeting of the German Gynæcological Society last summer the subject came up in an irregular way in the discussion of a paper by Elischer on the use of iodoform in severe laparotomies Dr Frommel had used the drug in two cases of tubercular peritonitis and in another case of ovarian tumor with ascites, with small papillæ all over the peritoneum Hirschberg had cured peritonitis with tubercular nodules by corrosive sublimate, hence iodoform was not necessary Dr Meinert agreed with the last speaker as far as iodoform was concerned, and threw doubt upon the sublimate, as a like result may be obtained by incision and tapping Dr Olshausen had seen it cured by incision, and threw doubt upon all that had been said before, by stating what we all know, that it may seem to get well of itself or remain stationary for years Dr Saenger gave curative value to laparotomy Dr Battlehuer had seen the same result follow tapping, finally, Dr Frommel, who had introduced this subject into the discussion, disclaimed that he had recommended iodoform as a specific for these cases

The credit of collecting the large mass of material relating to genital tuberculosis in general and to this phase of the subject in particular, belongs to Hegar [1] He reports two cases which were either cured or rendered stationary by laparotomy, another case of apparent arrest in which nothing special was done, and a laparotomy in a fourth case too recent to give results

Spencer Wells has had a like experience Koenig [3] reports a seeming cure, to the date of the report, using iodoform in the toilet of the peritoneum Neumann [4] had two cases Hegar [5] throws doubt upon the diagnosis of one of these cases, in which the woman remained well after an interval of eight years Potenmentions a case operated upon by Hartwig, of Hanover This subject seems to be, from the description, identical with my own A small portion of the peritoneum was excised and the diagnosis verified by examination Numerous miliary, granular and larger growths beset the membrane, which had lost its normal appearance Under the microscope a variety ranging from granular nodules to giant cell formation with cheesy masses were observed Bacilli were found located in the giant cell masses Ulceration was nowhere observed This case was characterized by slightly elevated evening temperature, but the tubercular process was not detected in any other organ One year after the operation the patient was well, with a great gain in flesh [6] Lindfors records a case of apparent cure In this instance there was no mistake in diagnosis, but a cyst was present, complicated by tuberculosis of the internal genitalia and peritoneum, the removal of which appeared too difficult to attempt This part of the operation was abandoned The abdominal incision seemed to render the tuberculosis stationary The case was not characterized by either amenorrhœa or high temperature [7]

Upon this brief history of laparotomy in its relation to tuberculosis of the peritoneum we may base a reasonable hope that in selected cases the operation may prove a bar to the progress of the disease, or if this is a too hopeful view of the matter, then for a period at least to afford the patient a fair degree of health and comfort It still further enlarges the field for exploratory laparotomy, and if the secret history of the operation could be written it would doubtless furnish a numerous array of cases in which similar results had, to the surprise of the operator, been reached It is safe to assume that opening the abdomen in instances of tubercular degeneration of its lining membrane is comparatively free from danger, and in view of its possible benefit amply justified Advanced tuberculosis of the internal genitalia and of the peritoneum has about it an appearance of malignancy that would forbid the operation were it not for the hope that the tubercular process might be rendered stationary, as a fatal result frequently follows exploratory incision in sarcoma or papilloma

In what way laparotomy tends to localize the tubercular process or render it stationary, or probably cure it, we are not in a position to say We may, however, in an oblique way throw some light upon the method In the form of tuberculosis to which we have particular reference there is a modified and peculiar form of inflammation, characterized by serous and plastic exudates, which opening the peritoneal sac may have a tendency to arrest, as a series of experiments in the surgical treatment of peritonitis now being made by various surgeons prove [8] The ascitic accumulation may, and probably does, prove an additional source of irritation, as we have already seen, in the debate before the German Gynæcological Society, that aspiration or tapping equally with laparotomy has been known to result in apparent cure Distension by the accumulation, aside from the irritating quality of its constituents, may act in a twofold way to intensify the morbid process mechanically by pressure, or as affording a medium for the distribution of the tubercular germs Bacilli may be found in the fluid, just as giant and polynucleated cells may be seen in the ascites of sarcoma "It is probable that these liberated cells graft themselves on the peritoneum and pass through the diaphragm into the pleura They behave just as we have seen bacteria do " [9] The explanation may exist in thorough evacuation of the fluid If this be true we see why tapping, equally with other methods, acts as a cure, and if true, drainage through a large opening and a thorough toilet of the cavity must be the better way We may trace the process a few steps

further The irritated peritoneum is given rest and allows of a process that belongs *per se* to tuberculosis, namely the thickening and induration of the surface—an encapsulation—and which Hegar[10] suggests may be a stage in spontaneous cure

The tubercular nodules do not always break down, but may form hard calcareous masses which remain in this condition indefinitely Such masses have been found in the peritoneal covering of the tubes [11] Both these processes, encapsulation and calcification, most probably are favored by the spontaneous absorption of the ascites which has been already noticed, or by its evacuation

One further reference to the natural history of tuberculosis need detain us but a moment When local it has been observed to undergo, without treatment either general or special, a so called spontaneous cure,[12] or in other words has become dormant, and may so remain for years Rokitansky, quoted by Hegar,[13] says this is very rare If tuberculosis was proved to exist in other parts such instances of unalterable localization are not known in literature Spontaneous so called cures are more common in men in whom the disease does not so readily extend to the peritoneum, but is more disposed to remain localized at the site of the initial lesion in the genitals than in women, as in the latter there is open communication between the peritoneum and the genitals, a region that in both sexes shows a marked tendency to initial infection, whence its easy transmission to the peritoneum, pleura and lungs as I have already shown When the newly formed products are in a condition of encapsulation, calcification, or caseous metamorphoses with absorption of effusion, the stand still ends as a rule by the eruption of the disease in other organs with fatal results, or by an intensified removal of the outbreak in the peritoneum As an element to give uncertainty to the effect of surgical treatment when followed by arrest of local symptoms of the disease in women, spontaneous cure may be considered of very doubtful value

It will be interesting to review briefly the form of tuberculosis of the peritoneum in which laparotomy may be expected to give the best results Kaulich,[14] in an elaborate study of the disease when confined to the peritoneum, divides it into three groups The first we may call the acute form, which advances by a series of attacks with pyrexia with intervening lulls, until the entire abdomen has been attacked, without effusion but with retraction of the abdominal walls There is no record of surgical treatment of this group, nor would it naturally fall under the observation of the laparotomist The second group is defined by an insidious invasion, slow and even advance without pyrexia, and with ascites as a leading and early trait, and unless we find evidences of consolidation at the apices of the lungs, which is often wanting, exceedingly difficult of diagnosis Our case belongs to this second group, and it is here that surgical treatment will offer its best results In this class also we get the apparent spontaneous cure, for Kaulich's third group is composed of the second which affords the phenomenon of decrease of effusion with general improvement, but only for a longer or shorter time If cases belonging to this second group can be brought under treatment before the secondary lung invasion, and the disease thus attacked midway in its advance from the genitalia to the respiratory organs we have an ideally typical case for laparotomy

We may go with surgical treatment much further than the second group as defined by my typical case Nodular masses may develop on the tubes and consolidate within the folds of the broad ligaments into fixed and irregular tumors, or the tubes may form elongated, round, uneven masses, but without the even circumscribed swelling of pyosalpinx Another form of tube infection is when broad ligaments, ovaries and tubes are consolidated into one mass in connection with a wide extension of miliary peritonitis Here Hegar, except in cases in which other and vital organs are involved, would advise salpingotomy and castration The uterus must be dealt with separately per vaginam with the curett, or caustics and iodoform, although Hegar treated one extra peritoneally The treatment by laporotomy offers some special difficulties that would not be met with in pyosalpinx The extirpation of the tubes is difficult owing to vascular and close adhesions and the arrest of hæmorrhage uncertain The tubes are involved in the posterior fold of the broad ligament and Hegar cautions against breaking through to reach them as it would probably result in irrepressible hæmorrhage Of course such extensive breaking down of vascular adhesions implies drainage in the after treatment It is doubtful if in such cases salpingotomy will meet with general favor Hegar's results are none too favorable to warrant such severe measures in search of a problematical cure He had one direct death, the third case developed secondary lung infection, the fourth and fifth cases also It will be a revival of all the hot discussions over total uterine extirpation in epithelioma with the same complication of after history

Briefly in conclusion, an analysis of my own case with a view to diagnosis will prove useful Let us consider the first symptoms that induced the patient to seek medical advice—the ascites Reasoning by exclusion the range of inquiry is not a wide one The face being free from œdema the kidneys are, as a rule excluded As a matter of fact they were healthy The heart exhibited no error, nor would the ascites point to any heart lesion The accumulation belongs properly to disease of the liver, as the lower extremities are free from œdema, the complexion, the evacuations, and the freedom of the hepatic space from pain, tenderness or enlargement prove that this organ is not the source of the effusion Examining the pelvis we observe the uterus to be in approximately a normal position and mobility, the vaginal vault free from tenderness, nodes or tumors, and on external palpation we find this true of the pelvic spaces generally We have thus eliminated

[14] Klinische Beiträge zur Lehre von der periton Tuberkulose, Prag Viertelj, II 36

benign cysts or tumors, sarcoma and other malignant diseases of the pelvis and abdomen as a source of the effusion Speaking with a due regard for the anomalism of disease we have only peritonitis left to explain the phenomenon, but the absence of febrile antecedents shows that it can be no ordinary form while the freedom of the lungs from any indication of tubercles simply renders uncertain what with this indication would be a fairly clear case Nothing is added to this history for months except occasional abdominal pain due to meteorism and pulmonary irritation which was self-limited, and a gradual wasting of the body Then on examination a state of affairs presents which can reasonably characterize but one thing The free ascites had become encysted In the whole range of pelvic and abdominal disease under the conditions named I know of none that will offer this peculiar anomaly except tubercle of the peritoneum This disease has one leading trait aside from fluid effusion and that is plastic exudation, hence the former must be followed after a certain interval by the latter with the result of widely encapsulating the effused fluid

Our case further demonstrates that miliary tuberculosis of the peritoneum may antedate the development of tubercular nodes and tumors upon the ovaries and tubes It may be that this is the rule and that the latter do not develop upon the pelvic organs except as the result of the evolutions from the stage of effusion to that of the adhesive exudate, and these masses being mainly the result of thickening and adhesions in mass this seems probable From the attention that the disease will attract, being now but another excuse for laparotomy, points like these will be cleared up

And lastly, as a positive aid to diagnosis we have the bacilli of tubercle It may be difficult to find these in the ascitic fluid Hegar found the bacillus but in the tubercle itself It would be reasonable to suppose, however, that a careful search would demonstrate its presence in the fluid

DISCUSSION

DR CHARLES T PARKES, of Chicago The paper just read by Dr Van de Warker is an admirable one Admirable in the description of the case related and upon which it is based, replete with pathological considerations of the subject discussed, complete in its collection of authorities, and just and reasonable in the deductions presented It is hardly possible that any of us have much experience from which to draw any conclusions for the cases of tuberculous peritonitis that have been subjected to this treatment are rare, so that the procedure so far as results go, is still on trial Some cases reported certainly seem to establish the supposition that laparotomy has been of more benefit in these cases than simple aspiration How this effect is brought about by the laparotomy does not seem clear One experience has happened to me, in which the exploratory incision in a doubtful case, led to the patient's recovery The patient had been sick many months and came under my care with a large mass in the abdomen which had many of the signs of an ovarian cyst She was reduced to an extreme condition of debility The incision showed the peritoneum much thickened and the abdomen free from a cyst, but filled with coagulated lymph There were no adhesions between folds of the intestines or between them and the abdominal walls It was removed in large masses by means of the hand and the cavity thoroughly cleaned A large drainage tube was left in the lower angle of the wound The patient passed on to complete recovery without any drawbacks Here was a case in which no matter how erudite the touch, how clear sighted the inspection or how exclusive the deductions, no proper realization of the patient's condition could possibly have been reached without abdominal section

The second case was one the exact fac simile of the case related by the author of the paper After many months' illness with a gradually increasing ascites the patient came under my care Careful examination failed to detect any cause for the ascites in the abnormal condition of any of the organs of the chest or abdomen Aspiration was done and when the fluid was withdrawn several irregular masses could be felt in the abdomen It was then concluded that the case was one of tuberculous peritonitis The abdomen refilled rapidly after the aspiration so that in one week it contained as much fluid as ever It was determined to do an abdominal section and establish permanent drainage When the abdomen was opened the peritoneum was found universally covered with nodules of small size The omentum was matted together in one mass of miliary tubercles, the internal genitalia were also covered with the same growths After emptying the cavity thoroughly and carrying a large drainage tube to the bottom of the cul de sac of Douglas, the wound was closed This was done two days ago and the patient seems not to have suffered any more from this procedure than from the aspiration The pain of distension is entirely relieved and there has been a very free flow of fluid from the drainage tube I feel better about this case since hearing the paper

Several cases of abdominal disease have come under my inspection in which in spite of every care in treatment and the most earnest attempts of good men to reach a clear diagnosis, the cases have gone on suffering for months and years and finally an abdominal section has shown a disease which could be removed and the patient cured One cannot say that because a patient has tuberculous peritonitis a laparotomy should be done with the belief that a cure will result Still I am convinced that the section promises more prolonged relief for the patient than can be expected from aspiration I am heartily in accord with the deductions of the paper

DR E P MURDOCK, of Chicago I was very much pleased with this paper and especially with the histories given by Dr Parkes, but I must say that the opposition side may as well be given, inasmuch as I call to mind two cases which came under my observation that did not terminate so well The first case presented a history similar to the last recited by Dr Parkes and was almost identical with the case cited in the paper, in which there was a slow accumulation

of ascitic fluid until the abdomen became much distended Finally she came under the care of a very prominent professor in this city who under a mistaken diagnosis performed laparotomy, emptying the cavity completely The patient recovered from the operation but the abdomen filled again just as bad as before Subsequently she came under my care and I drew off the ascitic fluid eight or ten times but it continued to refill She was tapped fourteen times She died within the last fourteen months and it was found to be a case of tuberculosis The laparotomy was of no benefit whatever

The other case first came under the care of Dr Hall, of this city, and I was called to see her afterwards She had been in the hospital at one time and presented a history of tuberculosis After having seen the effects of these other operations we decided not to perform laparotomy The abdominal cavity was aspirated repeatedly, upon the theory given in the paper that perhaps some relief might be given by aspiration, but the abdominal cavity continued to fill, after which tuberculosis developed in the lungs and the patient died

From these two cases it seems, while laparotomy may give relief, where the disease cannot be removed, if tuberculosis exist and the tubercles cannot be taken away, I cannot see how we can hope for a cure of the cases by simple laparotomy Of course we can relieve the distension, but we can do the same by aspiration There may be some cases where an effusion of peritonitis is partially absorbed and some remaining in the abdominal cavity is cleaned away, where undoubtedly the disease is removed and the laparotomy proves a success because the patient is cured, but if there be tubercles remaining in the omentum or mesenteries I cannot see how there can be any benefit derived from laparotomy

DR E W CUSHING, of Boston I have a case to report which is of interest in this connection as it was an undoubted case of tuberculosis and underwent laparotomy The woman came to me complaining of vomiting She was sent to me to have the matters vomited examined I examined her and found a retroversion of the uterus I treated her awhile after that, supporting the uterus with tampons, but she got no better, was always vomiting, nothing would stay on her stomach Finally she was admitted to the hospital Her temperature was about 99½°, sometimes more sometimes less At first the uterus was movable but afterwards it was fixed, and there was a hardness in the region of the tubes and in the roof of the pelvis, her condition was getting desperate There was no trouble in the lungs, and it seemed probable that it was a case of salpingitis Laporotomy was made and upon opening the pelvis it was found to be filled with fluid which was clear and straw colored The whole perineum was completely studded with little granules On examining the ovaries and tubes it was found that they were in a mass of adhesions apparently of a tuberculous material A diagnosis was made of tuberculosis peritonitis The wound was closed after thoroughly washing out the cavity with a bichloride solution She recovered and the vomiting ceased Six months afterwards she came to the hospital complaining that one of the stitches in the abdomen was discharging It was found that the lower part of the abdomen was filled with a mass which came up to the abdominal opening half way between the pubes and the navel Some little treatment was made and she went back to Ireland The operation was last December and we got a letter from her the other day saying that she was entirely well She has not entirely filled up with the fluid since, but the disease is there and will some day kill her I think before we take the risk of removing ovaries and tubes that are clearly tubercular it is well to wait for the history of those cases that have been operated upon

I have two other cases which bear on the fact of the fluid not coming back after laparotomy One is interesting because of the difficulty of diagnosis The lady was supposed to have catarrh of the stomach, there was a gradual filling up and great difficulty in breathing Dr J saw her and said it might be an ovarian cyst, tubercular peritonitis or chronic laryngitis When they sent for me she was so she could not lie down and we concluded it was best to make a laparotomy The abdomen was opened and a large amount of fluid drawn off We found cancerous masses deep down, around the omentum and the ovaries The wound was closed and permanent drainage established, but nothing ever came through the drainage tube The lady lived five months and never had any return of peritoneal fluid

Another similar case that Dr Marcy and I operated on was *in extremis* from the tremendous extension of the abdomen, she must have weighed 300 pounds We lifted her on the table handling her as we would an iron safe The fluid was removed and permanent drainage established It was found that there was a cancerous trouble She was relieved and gradually died from the natural progress of the disease

I think that in these cases it is good surgery to open the abdomen, I do not believe in tapping or puncturing I believe thoroughly in opening the abdomen and seeing what there is to deal with I think it is premature for us to follow Hégar's example of trying to take out the ovaries and uterus until we see how these cases come out

DR A S V MANSFELDE, of Ashland, Nebraska I wish to make a short statement The author of the paper is correct in doubting the efficacy of iodoform or corrosive sublimate in tuberculosis of the perineum I may add that it is only within the last two weeks that experiments have been made positively proving the absolute uselessness of iodoform in tubercles whether of the joints or perineum It will not harm the germs, they will grow where the iodoform is A mixture of tubercle with iodoform put into the chamber of the eye will more quickly develop tuberculosis than the tubercle itself My authority is the late experiments in the laboratory of Berlin I think I can offer an explanation why laparotomy will cure tuberculosis of a peritoneal nature You are aware of the fact that in chronic hyperæmia of the lungs caused by some disease of the heart it is very seldom if ever found to be tuberculous It is

also a clinical fact that wherever a vesical cavity is cured, outside of a few cases of calcareous degeneration, the greater number of cases are cured by fibroid thickening of the surroundings of the tubercle cavity, thus stopping the progress Now is it not a fact that when you make a laparotomy you remove the very cause of the tuberculosis You cause by this operation the same condition of things which nature has produced in cases of chronic progressive heart disease, hyperæmia and consequent strangulation of the existing growth on the surface of the perineum, and rapid change for the better

THE FUNCTION OF THE OBLIQUE MUSCLES IN CERTAIN CASES OF ASTIGMATISM

Read in the Section on Ophthalmology and Otology, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY G C SAVAGE, M D,

PROFESSOR OF OPHTHALMOLOGY AND OTOLOGY MEDICAL DEPARTMENT VANDERBILT UNIVERSITY NASHVILLE TENN

So much has been said and written about astigmatism that it would seem that nothing more of a practical nature could be added

Before proceeding to the study of the function of the oblique muscles in certain forms of astigmatism, I would briefly review what has long been known The rule, with many exceptions, is that astigmatism is due to the radius of curvature of the vertical meridian of the cornea being shorter than the radius of curvature of the horizontal meridian The exceptions are that the meridian of greatest curvature may be horizontal or may be at any degree between the vertical and the horizontal The meridian of least curvature is always at right angles to the meridian of greatest curvature In hypermetropic astigmatism, whether simple or compound, the best meridian is usually vertical or within 45° of the vertical, in myopic astigmatism, as a rule, the best meridian is horizontal or within 45° of the horizontal In the one instance horizontal lines or those nearly horizontal are best seen, while in the other, vertical or nearly vertical lines are most distinct It is well known that, other things being equal, astigmatism is least troublesome to a patient if the best meridian is vertical, as in hypermetropic astigmatism, or horizontal, as in myopic astigmatism In all other cases the nearer the best meridian is to the vertical or to the horizontal, the more favorable it is to the patient's comfort

More than two years ago my observation of hypermetropic astigmatics led me to the conclusion that there is less discomfort to patients, if the best meridian of one eye is on one side of the vertical, *e g*, at 100°, and the best meridian of the opposite eye is on the other side of *the vertical e g*, at 80°, than if both were on the same side of the vertical A similar study of myopic astigmatism respecting the relative positions of the best meridians and the horizontal, led me to a like conclusion I was not long in surmising that the oblique muscles must have something to do in cases of astigmatism where the best meridian is neither at 90° nor 180° What this function is I now no longer surmise, having observed it often It is to so rotate the eye on its antero posterior diameter as to bring its best meridian *to the vertical* or to the horizontal The oblique muscles, at best weak, soon become fatigued, and if not allowed to rest must become the source of great discomfort For some time I was in doubt as to how they acted It is now clear that the superior oblique of one eye must act with the inferior oblique of the other, the one muscle *under the control* of the fourth nerve, the other under the control of a branch of the third nerve, otherwise double vision would result, as I am able to show by means of these diagrams The rotation of one eye towards, and of the other from, the median line, keeps corresponding parts of the retinæ in the same relative position, hence the images of external objects fall on parts of the two retinæ that act together

Let us study why it is that the condition is more favorable if the best meridian of one eye is at 100°, and the best in the other at 80°, than if these meridians were, in both eyes, at 100° or 80° If the best meridian of right eye be at 100° and *that of left eye* at 80°, the right superior oblique will roll the globe 10°, thus bringing the best meridian to the vertical, the most favorable position, the left inferior oblique will roll its eye out 10°, thus placing its best meridian at an angle of 70°, not so favorable to sharp sight as its natural position The better image in *the right eye is the one the* brain takes cognizance of for the time Soon the labor is shifted, in time too short to be computed, from the right superior and left inferior oblique to the left superior and right inferior oblique muscles, when the best meridian of the left eye is brought to the vertical, and the best meridian of right eye is turned to an angle of 110° Now the sharper image is on left retina, and is the one the brain takes cognizance of until the labor is again shifted This state of activity on the part of the oblique muscles alternates with the state of rest, and, consequently, the fatigue is less than if a state of tonic contraction had been kept up

If the best meridian of the two eyes be at 100°, the superior oblique of the right eye and the inferior oblique of the left eye will roll their respective eyes so that, at the same moment, the best meridian of each eye is vertical Other things being equal, an equally sharp image is formed in the two eyes A state of tonic contraction on the part of these muscles is necessary so long as anything approaching accurate vision is maintained This is necessarily attended by much fatigue and in many cases by suffering

If the best meridians are near the horizontal in the two eyes, the one at 170° in the right and the other at 10° in the left eye, then the oblique muscles will so act as to place first the best meridian of one eye and then the best *meridian of* the other horizontally, etc, as I have shown in the conditions where the object of the rotation was to get the best meridians in the vertical position

This habit of rotation is formed in early life, and, unless the condition on which it depends is cor

rected, is continued throughout life, the symptoms caused by this rotation have, therefore, a duration commensurate with one's existence Not so with those symptoms caused by what is ordinarily known as eye-strain, for at the age of 60 years, a little earlier or a little later, the ciliary muscle has lost all its power, therefore the symptoms due to the exercise of this power have vanished, the loss of this ciliary power being gradual, the symptoms disappear by occurring at longer intervals and being less severe

As I have demonstrated to you, the action of the oblique muscles in giving to certain astigmatics a condition of things favorable to sharper sight, is harmonious but not symmetrical, the superior oblique of one eye acting with the inferior oblique of the other, just as the internal rectus of one eye may act harmoniously with the external rectus of the other, *e g*, with my face fronting the end of this room, if I look to the right the external rectus of my right eye acts with the internal rectus of my left eye in directing the visual axes toward the object at which I may be looking The action is harmonious but not symmetrical

If I fix my vision on this page before me my visual axes are directed towards it by the symmetrical and harmonious action of the two internal recti muscles In like manner the action of the oblique muscles is, under certain conditions, symmetrical and harmonious, as was long ago pointed out by physiologists The superior and inferior recti approach the eyeball obliquely and are so attached When they contract they not only cause the eye to revolve on its horizontal diameter, but they also cause a slight revolution to take place on the antero-posterior axis If the vision be directed upwards the superior recti, acting harmoniously as they always do, not only make the visual axes point up but, on account of the obliquity of their attachments, they would rotate, if unopposed, the two eyes on their antero posterior axes so as to make the upper end of the vertical meridian of each eye turn towards the nose, and thus would produce double vision This action is opposed by the two inferior oblique muscles, which are thrown into a state of harmonious and symmetrical contraction, each keeping the vertical meridian of its own eye in its normal position, thus preventing double vision I may say here that the branches of the third nerve supplying the superior rectus and the inferior oblique muscles deserve if any nerve does, the name "patheticus," which in no sense belongs to the fourth nerve

When the gaze is directed downwards the inferior recti would not only turn the eyes in that direction but, if unopposed, would also so rotate the eyes on their antero-posterior axes as to turn the lower end of their vertical meridians towards the nose In this condition the superior oblique are the muscles that oppose and by their opposition keep the vertical meridians parallel In speaking above of the harmonious and symmetrical action of the oblique muscles I have had in mind an emmetropic eye Physiology very properly lays stress on this kind of action on the part of these muscles and, with a single exception, it is the only function ascribed to them by physiologists The exception is this If the head be turned to one side, the eyes being emmetropic, the oblique muscles will act harmoniously but not symmetrically in so revolving the eyes as to compel the vertical meridian still to remain vertical notwithstanding the inclination of the head, *e g*, supposing my own eyes to be emmetropic this teaching would lead me to believe that, if I were to incline my head 15° towards the right, the right superior oblique and left inferior oblique muscles would each so act on its own eye as to revolve it through an arc of 15° to bring the naturally vertical meridians back to the vertical position, a thing not necessary, nor do I believe it ever occurs I am certain it does not occur in astigmatic eyes made emmetropic by means of a proper cylinder Suppose, as is nearly true in my own case, that a man has simple hypermetropic astigmatism, the perfect meridian being at 90° He has been given the proper convex cylinder with its axis, of course, at 90° To all intents and purposes his eyes are now emmetropic Let him incline his head 15° Should his oblique muscles now rotate his eyes 15° his vision would be made worse, in the same manner as revolving his glasses through an arc of 15° Since this does not occur, as I personally know, for I can see as sharply with my head inclined as when it is erect, I conclude that harmonious non symmetrical action of the oblique muscles has no existence in emmetropic eyes, whether naturally so or made so by means of proper correcting glasses

I feel that I can say without fear of successful contradiction that the real and only harmonious non-symmetrical action of the oblique muscles of the eye is that, already pointed out by me in this paper, for rendering sharper the acuteness of vision in certain forms of astigmatism

The most beautiful part of this theory is that it has a practical side For two years it has been of incalculable benefit to me, enabling me, in many instances, to do successfully work that had been a failure in the hands of others One remarkable case is, at this moment, in my mind About 10 years ago a lady, then about 25 years old, consulted a reputable ophthalmic surgeon for symptoms which she had been led to attribute to her eyes He found one eye useless from an old central choroiditis, but the fundus of the other eye was perfectly healthy The good eye, however, had compound hypermetropic astigmatism with the best meridian of the cornea, as he determined it, at 180° He justly attributed her symptoms to this defect and prescribed a spherocylindrical lens for its correction, placing the axis of the cylinder at 180° For months this lady persevered in the use of her spectacles, obtaining no relief At last, in despair, she laid them aside About 8 years later she was encouraged by some of her friends for whom I had done some refracting work to consult me I examined the glass given her by the surgeon referred to above, determined its strength and the location of the axis of the cylindrical part Under homatropia I made a most careful examination After the exercise of much patience and perseverance, I determined that the best meridian was at an angle of 165° and not at 180° I

prescribed for her, as I now remember, the same glass that had been given her before, placing its axis, however, at 165° After a few days of adaptation, she became comfortable and has remained so ever since, a period of almost two years The error made by the former surgeon can be accounted for in no other way than that the superior oblique (it was her left eye) had rotated the eye through an arc of 15°, so as to bring its best meridian to the horizontal Without a knowledge of this rotation, he hastily completed his work The demand for rotation still existed after the glass had been given her, and was even more urgent than before, for now the rotation would bring perfect vision Her symptoms continued, for the cause was not removed A knowledge —at that time vague—of this tendency to rotate made me exceedingly careful in placing the axis of her cylinder Vision being now perfect without rotation, the habit was soon broken and ever since she has been comfortable I might refer to other cases, but such reference would occupy too much time

The correction of astigmatism would be as easy as its detection were it not for this tendency to rotate As it is, there is nothing more difficult in ophthalmic practice than the correction of astigmatism when the best meridian happens, as is frequently the case, to be out of the vertical or the horizontal In some cases this tendency to rotate is so persistent that hours of patient work may be necessary for determining the best direction for the location of the axis of the cylinder The strength of the needed cylinder is nothing like so difficult to determine The rotation is not likely to be so persistent when the eye is under the influence of homatropia and when the other eye is covered, as when no medicine has been used and both eyes are allowed to look If the best meridian is at 90° or 180° there can be no difficulty in placing the axis of the cylinder, for the patient's answers will always be the same, the habit of revolving never having been formed

If after most careful work the patient can at no time decide between the two points of 100° and 105°, the point chosen must be at 100°, for it is nearest the perpendicular, the direction in which the eye has always rotated If it happens to be wrong, it will result in partial relief, for the globe will not have to revolve so far as before in order to be the best vision, and the rotation is in the same old direction But if the best meridian is at 100°, and the axis of the cylinder is placed at 105°, the condition after is worse than the condition before the glass was given, for the direction of the rotation must be changed, though the arc to be described is less What is true when the best meridian is near the vertical is also true when it is near the horizontal

The arc between the best meridian and the vertical or horizontal, as the case may be, is often too great to be described by the rotation of the eye resulting from the contraction of one of its oblique muscles In this case an inclination of the head will aid vision We will suppose that the best meridian of the right eye is at 45° I do not believe that the inferior oblique muscle could rotate the eye through so great an arc, but aided by leaning the head to the right the best meridian can be readily brought to the vertical The head may incline 25°, leaving an arc of only 20° through which the eyeball must rotate in order to complete the 45° This leaning of the head as well as rotation of the eyeball are alike involuntary, each being under the control of the guiding sensation in the retina

The inclining of the head by astigmatics I do not claim as an original observation, but the observation of the function of the oblique muscles in certain forms of astigmatism I do claim for myself I believe the observation both correct and practical

---

THREE CASES OF SCIATICA

BY J W BROWN, M D,
OF SILVERTON, COL.

Case 1 —In May, 1884, I was consulted by A P, about 30 years of age, a tinsmith He had been suffering over a year from sciatica His ailment was of a subacute character, but it was subject at times to aggravation As a general thing he was able to follow his occupation, though he was never free from pain and constantly limped in his walk He had been subjected to anti rheumatic remedies, antiphlogistics, and counter irritation by the use of fly blisters, liniments and frictions, and at times, for the allaying of acute suffering, morphine by the hypodermic syringe was used I had ministered to him several times for this ailment without accomplishing a satisfactory result He came to me the last time to be relieved from the suffering incident to an aggravation of his trouble I prescribed 1 drop of croton oil made into 2 pills, with the extract of gentian as an excipient, and ordered him to take both pills at one dose The result was a profuse watery discharge from the bowels which brought with it an abundance of scybalous lumps He was almost entirely relieved of his pain and lameness at once, and remained so for several days, so that I had hopes that a complete cure had been effected But the pain and lameness gradually returned, and in about 10 days he was as bad as before I again administered the croton oil, with the result of a similar watery discharge and hard lumps of fæcal matter as before, and again there was relief from pain and lameness, but the sciatica again returned after a few days I concluded that the trouble might be due to the presence of scybala in the rectum or sigmoid colon, the result of constipation, and I prescribed a preparation consisting principally of cascara sagrada, which gradually induced a regular daily habit of sufficient discharge from the bowels, and complete cure of the sciatica

Case 2 —W T, a miner about 43 years old He was injured in February, 1885, while handling timber In tumbling a piece of timber over others, one end of it bobbed up and struck him fairly in the sacro ischiatic notch He fell to the ground in agony and was carried to his bunk in the miners' cabin I had to make a mountain climb of 1,500 feet to reach him I used morphine hypodermically and left morphine powders The next day he was no better The pain was only slight while he remained perfectly still, and

kept the affected limb propped in a certain fixed and semiflexed position, but when he moved the limb, however slightly, a streak of excruciating pain shot down the sciatic nerve and he shrieked with agony On this second visit I applied a blister a foot long down the thigh over the sciatic nerve, and left instructions for its after care I was afraid to use cathartics on account of the patient's inability to manage himself in case catharsis should not bring relief with it, and the use of the croton oil would have been extreme desperation The blister had no appreciable effect My patient was no better than the first hour he was injured, and on my third visit I was in a mood to resort to desperate measures I was getting tired of making a daily mountain climb of 1,500 feet without accomplishing anything, and I went on this third visit armed with 2 pills containing 1 drop of croton oil I found my patient propped in the position he had early found to be the easiest He was not the least improved in his condition, and he was in the constant exertion of a positive mental and muscular effort to keep himself absolutely still He was becoming worn in consequence of this constant effort to avoid the agony incident to the least motion I pondered over his case awhile and over the dire catastrophe which would follow the giving of the croton oil if it should not bring relief with the catharsis I finally resolved that I would administer the croton oil and that my patient must look after the fæces in such manner as his ingenuity might devise I took the pills out of my pocket, and saw my patient swallow them, and then I discreetly retreated down the mountain The result was wonderful So soon as it was necessary on account of propriety that my patient should run he was able to do so He was cured absolutely, immediately, and as if by a miracle He has never suffered a stitch of pain from that trouble since, and the third day following he went to his regular work This was a case, probably, of acute inflammation of the sciatic nerve due to a direct blow, and the mode of relief was extreme depletion consequent on the violent catharsis, conjoined with the counter-irritation of the croton on the mucous membrane of the bowels

Case 3—W A, a miner, about 42 years of age He had had two attacks of sciatica before, the first lasting 4 months, the second 3 months He consulted me in May for his third attack of sciatica The pain was not acute, but was of a dull, aching variety which was increased in severity by walking His gait had the characteristic lameness associated with this affection He said his bowels were regular He might have meant that they were regularly constipated, as the fæcal discharge was scybalous and scanty, though he had been having a daily evacuation I prescribed 1 drop of croton oil in 2 pills, with instructions to take 1 only He took the pill about 8 o'clock in the evening and was kept busy making excursions to and from the water closet until the next morning His pain and lameness disappeared entirely for a time, but gradually returned during the 2 or 3 days following, and he took the second pill without being instructed to do so This pill acted similarly to the first, but not so severely, and he was again relieved for a time only, the pain and lameness gradually returning I then ordered a pill nightly of nux vomica, hyoscyamus and aloes, which was ineffectual, and I prescribed pills of the extract of cascara sagrada, each 2 gr, with instructions to take enough each night to produce a free daily evacuation The use of the cascara finally induced a daily habit, and in the course of 10 days the sciatica gradually left him, ending in a complete recovery

These cases are cited to show that sciatica is not always rheumatoid, but is frequently dependent on simple constipation the correction of which cures the sciatica The use of the croton oil produces a thorough clearing out of the large intestine and gets rid of all retained lumps of fæcal matter The return of the sciatica is due to the reaccumulation of scybala, which produces by irritation or pressure on adjacent nerves a reflected neuralgia down the course of the sciatic nerve, sometimes for its whole length

The use of croton oil in these cases is not original with the writer In 1875 Prof Donald McLean, of Ann Arbor, had a case of sciatica of 2 years' standing in the clinic One drop of croton oil cured his case almost instantaneously, and hence the use of it in the cases above cited The writer was a student at Ann Arbor during the following session, and Prof McLean related the facts of his case to the class Regarding the use of the croton as a severe remedy not devoid of possible bad results, the writer was afraid to use it for several years in such cases as above cited, though the opportunity had presented itself several times Finally necessity compelled its use, and with such remarkable results that the history of these cases has been thought worth a careful study In the absence of intestinal or stomachic inflammation, subacute or chronic, or hyperæmia conjoined with hyperæsthesia, the use of croton is probably quite safe, but of course, in all cases, the oil should only be used after careful elimination of the possibilities of disaster

Silverton, *Colo*, *July 27*, 1887

MEDICAL PROGRESS.

SURGICAL TUBERCULOSIS —(See the preceding number of THE JOURNAL) After treating of "Tuberculosis of the Skin, and Connective Tissue" VOLKMANN takes up II *Tuberculous Affections of Mucous Membranes accessible to the Surgeon*

7 *Tuberculosis of the Tongue* appears partly in the form of ulcerations of a sometimes torpid, sometimes more fungous character, and sometimes in the form of deep-reaching knots (Knoten) which gradually soften at the centre Solitary tuberculous *ulcers of the tongue*, with fungous growths and somewhat indurated surrounding, may be *easily* mistaken for carcinoma when the trouble appears in an elderly person I have twice made that diagnostic mistake, and the error was only discovered by the microscope after extirpation of the diseased

part The subsequent history of these cases confirmed the microscopic diagnosis The knotty (or nodular, *knotige*) form of tuberculosis of the tongue, on the other hand, is at the beginning hardly to be distinguished from gummous affections of the tongue In their subsequent course the cheesy purulent softening of the knots and the transformation into a characteristic abscess, their way of breaking and the whole further course of the affection will leave no doubt as to the character and significance of the trouble The great majority of the cases operated on by me, partly by scraping out and by the application of the thermo cautery, and partly by removal of a wedge shaped portion of the tongue, have probably succumbed later on to pulmonary tuberculosis Some of them have, certainly, remained perfectly healthy for years, even when belonging to strongly hereditarily affected families Whether there are tuberculous processes of the tongue that should be rather classified as lupus remains to be seen

I have twice by autopsy of patients, that suffered from tuberculosis of bone and died of pulmonary tuberculosis, found the entire surface of the tongue covered with perfectly superficial, confluent tuberculous ulcerations, from the size of a pin's head to that of a flax seed, between which were everywhere scattered characteristic miliary tubercles The process had only appeared in the last few weeks before death, and had been taken for aphthæ

8 *Tuberculosis of the Pharynx and Palate*—I have seen almost exclusively in young persons, about the period of puberty and shortly after it Flat, confluent ulcers, as large as a millet seed and larger, with yellow base, spreading from the palatine arch over the posterior wall of the pharynx and the whole posterior surface of the velum palati By strong light it is generally possible to discover the miliary tubercles between the separate ulcers The affection is easily mistaken for congenital syphilis

The extensive adhesions of the cicatricially contracted velum palati, with complete or almost complete exclusion of the pharynx from the nasal cavity, and certain forms of cicatricial stenosis of the pharynx immediately above the larynx, are oftener to be referred to healed up tuberculous ulcers than to syphilis In its severe forms the latter produces rather defects on the palate, whilst tuberculosis produces extensive ulcerating surfaces which are specially prone to cause adhesions later on

Energetic surgical treatment is easier to institute and decidedly more promising than in laryngeal tuberculosis Probably most of the patients die of pulmonary affections before the pharyngeal tuberculosis is cured, even if they be not already suffering from pulmonary disease, but permanent cure by early local treatment with caustics, the hot iron, scraping, etc , certainly does take place, and I have repeatedly observed it

9 *Ozæna tuberculosa*—There is an ozæna tuberculosa, caused by the formation of true tuberculous ulcers in the nasal mucous membrane, and which is to be sharply distinguished from the very much more frequent so called rhinitis scrophulosa, which is simply caused by catarrhal conditions Still more seldom do primary tuberculoses of the osseous structures of the nose, particularly of the upper jaw, secondarily lead to infection and specific diseases of the nasal mucous membrane

10 *Tuberculosis of the lips*—I have twice seen severe tuberculous (not lupous) ulcerations on the lips Once in the case of a young girl with multiple focus tuberculosis (Herdtuberculose) and sound lungs, and once in the case of an elderly lady In the first case the deeply reaching ulcer was removed by a wedge shaped incision, and in the second case the more flat ulceration, surrounded by thick crusts and sclerosed connective tissue was mistaken for a carcinoma, and was maltreated with superficial cauterizations In this case excision and a plastic operation were necessary

11 *Fistula in Ano*—Some rectal fistulas already have the significance of tuberculous ulcers The relation between rectal fistulas and tuberculosis of the lungs, so strongly emphasized by the older surgeons is explained, or rather corrected, by this fact The tuberculous fistula in ano differs from the non-specific by its tendency to form great masses of fungous granulations, widespread loosening of the mucous membrane and undermining of the outer skin, as well as sinuous abscesses

The treatment must therefore be the same as for tuberculous abscesses free incision, scraping out of the fungous granulations, removal of the thin strips of skin and mucous membrane, open treatment by packing in antiseptic gauze, especially iodoform gauze In obstinate cases energetic cauterization with the hot iron should also be used

12 The analogue of tuberculous rectal fistula is found in the rare cases of insidiously developing perityphlitis It begins after the perforation of a single specific ulcer of the intestine, in otherwise still healthy persons who up to this time have presented no symptom of intestinal tuberculosis, and runs its course in the same way, forming large tuberculous abscesses, multiple fistulas, and extensive solutions of the skin, and also with the production of massive tuberculous (fungous) granulations —*Langenbeck's Archiv*, Bd xxxiii, Hft 1

OATEN FLOUR IN THE TREATMENT OF BURNS — MR G GREENE says The comparative success attendant on the adoption of the following line of treatment, together with the fact of my being unaware of its having been advocated before, is my reason for bringing the matter under the notice of the profession Different treatments have been from time to time suggested with the object of favoring the healing of burns and scalds with in many instances questionable results I have for some time been in the habit of using for all degrees of these injuries equal parts of fresh lard (that is, free from salt) and oaten flour made into a paste, which, when spread on a cloth (old calico), or preferably a piece of lint, I direct to be applied or rolled round the affected part or limb, and allowed to remain on twenty four hours, after which a fresh application is made, and so on every twenty-four or forty-eight hours, as the exigencies of the case

demand In every instance I was well pleased with the progress of cases subjected to this treatment, several of which had been ineffectually treated by other methods

The advantages which I claim for this application are (1) its freedom from odor, (2) its soothing properties and antiseptic action, (3) its superior healing powers, and lastly, its cheapness and the ease with which it can be procured (in most houses) on the shortest notice This latter advantage is of no small importance, taking into consideration the sudden and frequent occurrence of injuries of this nature in ordinary domestic life —*British Medical Journal*, Sept 24, 1887

ERGOTIN AS AN ADJUVANT TO DIGITALIS —ROSENBACH, in the *Berliner klinische Wochenschrift*, No 34, 1887, reports good results from the combination of these remedies in (1) aortic insufficiency, (2) in idiopathic dilatation of the heart, with alterations in the elasticity and contractile power of the blood vessels, (3) in arterio sclerosis

He suggests the following formulæ

℞ Inf sec cornu	ʒ2½
Æther sulphur	♏45
Acid hydrochlor	♏15
Aquæ	℥3½ —M
Sig Teaspoonful every two or three hours	

Also	
Ergotin	gr 30 to 60
Acet digital	♏75
Aquæ	℥1½ —M
Sig Tablespoonful as indicated	

In pill form	
Ergotin	gr 45
Pulv fol digital	gr 30
Pulv et ext gentian	q s
Ad pil 50 in num	
Sig Dose two or three pills	

Also	
Infus fol digital	♏23
Ergotin	gr 30
Aquæ	℥4½ —M
Sig Teaspoonful every two hours if needed	

—*Medical News*, Oct 15, 1887

CREASOTE IN THE TREATMENT OF PULMONARY PHTHISIS —FRAENTZEL has used this remedy since 1878, chiefly in cases without fever, cough, or complications The following formula was employed

Creasote	13	parts
Tincture of gentian	30	"
Brandy	250	"
Sherry, enough to make	1,000	" filtered

A tablespoonful is given two or three times a day, in a glass of water, and at the same time two tablespoonfuls of cod liver oil are given daily The patients are kept, day and night, in freely ventilated rooms and are fed abundantly Improvement is manifested by gain in weight, increase of the appetite, diminution of the cough, expectoration, and pain, a reduction of the area of dulness, and the disappearance of bronchial souffles Out of 400 patients treated by this method, 150 have been permanently benefited —*N Y Medical Journal*, Oct 22, 1887

ICTERUS NEONATORUM —SILBERMANN (*Arch f Kinderheilk*, Bd 8, cited in *Fortschr d Med* No 19) has studied the subject of icterus neonatorum, and arrived at the conclusion that it is a jaundice of reabsorption and of hepatogenous nature The bile stasis occurs in the bile capillaries and interlobular ducts, which are compressed by the dilated branches of the portal vein and blood capillaries of the liver The congestion of these vessels is brought about by the changes in the hepatic circulation that arises soon after birth, which is one effect of a general change of the blood plasma This blood change is a sort of fermentation depending upon the destruction of red corpuscles shortly after birth The icterus is more marked in the more feeble infant, for in it the blood changes are more considerable than in the strong The destruction of red corpuscles and their accumulations in the hepatic vessels afford material for the formation of bile in excess —*Lancet*, Oct 15, 1887

CREOLIN VS CARBOLIC ACID —E VON ESMARCH, assistant in the Royal Hygienic Institute of Berlin, has made a series of experiments with creolin, a new disinfectant, which has been highly spoken of by Professor Frohner of the new Veterinary School of Berlin Dr von Esmarch made a number of comparative observations with carbolic acid on the disinfecting, deodorizing, and antiseptic properties of creolin Amongst other observations, he noted the effects of the two substances on fluids containing cholera, typhus, and anthrax bacilli As a rule, creolin appeared to be much the more active Similarly the offensive smell of various putrefying liquids was controlled much more readily by creolin than by carbolic acid Creolin soap, too, showed itself more active as a disinfectant than corrosive sublimate soap —*Lancet*, Oct 15, 1887

THE TREATMENT OF ABORTION IN THE OBSTETRICAL CLINIC OF FLORENCE —FASALA has observed the following rules in the treatment of abortion, with good results

1 An expectant course is pursued when the cervix uteri is closed and can be dilated with difficulty, and if no signs of decomposition of the fœtus are present

2 Under conditions favorable for the introduction of instruments or the hand, the ovum and its appendages are promptly removed

3 If decomposition has begun, the cervix is dilated by laminaria tents or metallic dilators, and the ovum is removed

4 Intra uterine injections for antisepsis are made with warm solutions of bichloride of mercury, 1 to 2000, in case of hæmorrhage, hot solution of bichloride of mercury, 1 to 4000, and tamponing the vagina, are used —*Annali di Obstetricia*, March, 1887 *Medical News*, October 8, 1887

GALVANISM IN ULCER OF THE TONGUE —In the *Paris Médical* of July 23, is a report of a case of ulcer of the tongue cured by the continuous galvanic current The treatment required 18 months and 109 *séances*

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE $5 00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible remittances may be made at the risk of the publishers by forwarding in REGISTERED letters.

THE TEXAS SPECIAL COMMITTEE ON SURGERY

Some years ago an English medical weekly asked "What good (professionally, that is) can come out of Texas?" Even had this question not been answered before, a sufficient answer may be found in the two first reports of the "Special Committee on Surgery of the Texas State Medical Association" Besides the matter contained in them these reports, for 1885 and 1886, show three things that the surgeons in Texas recognize and do their duty to the profession by contributing to the stock of common knowledge, that the Texas State Medical Association is fully alive to the interests of the profession in appointing such a Committee, and that a State medical association can find a committee to do good work

The first report contains, so far as the records could be had, a statistical summary of all the surgical operations performed in Texas up to 1886—4,293 operations being tabulated The report for 1886 contains a tabular statement of 1,046 operations The death rate of all operations up to 1886 was 8 15 per cent , the mortality for the 1,046 operations for 1886 was 7 93 Beginning with amputations of the thigh we find that the mortality of the 150 operations performed was 36 per cent Five double amputations of the thigh gave 1 recovery Of the 54 fatal cases antiseptics were not used in 41 cases Of the cases that recovered antiseptics were used in 37 cases From the make up of the report it seems that antiseptics may have been used in some cases in which it is not stated Eighteen cases died in 24 hours or less, 4 died of pyæmia or septicæmia, 3 of gangrene, from neglect in 2 cases, 2 died of tetanus, and 1 had tetanus and recovered, 1 died of pulmonary congestion from ether, 1 died of erysipelas, and in 24 cases the cause of death is not stated In 37 cases the operation was performed for railway injury, gun shot wound, or other severe traumatism The anæsthetic was chloroform in 130 cases, ether in 8 cases, and chloroform and ether in 11 cases, not stated in 1 case The shape of the flap is not stated in many cases, nor is the time after injury at which the operation was performed Inasmuch as the date of operation is not given in the first report it is, of course, difficult to form an accurate opinion of some things regarding the operations

Of 97 amputations of the leg 37 died, 18 78 per cent , 8 double amputations with 2 deaths, 1 being complicated by a railway injury to the head, the other a double operation on leg and thigh for railway crush, and died of shock Antiseptics are mentioned in connection with 65 operations, of which number 18 were fatal—29 38 per cent Five cases died of shock, 1 case of triple amputation, both legs and one hand, died of exhaustion in 2 days, 3 died in 24 hours, 3 of secondary hæmorrhage, 3 of tetanus, 1 died on 30th day, having passed from operator's care on 10th day, 6 died of pyæmia and septicæmia, carbolic acid being used in 4 cases, the operation being performed for compound dislocation of ankle, necrosis and gangrene from old gun shot wound, chronic ulcer and necrosis, compound comminuted fracture of both bones (never rallied from shock), gangrene, and old ulcer, 1 died of exhaustion after amputation for senile gangrene, 1 of exhaustion and dysentery, the operation being for railway injury, 1 of gangrene, operation for railway injury, 1 from cachexia in 40 days, operation for cancer of heel, in the other cases the cause of death is not mentioned

Thirty two disarticulations of the shoulder gave 4 deaths—12 5 per cent , the operations being performed for gun shot wound, gangrene after wounds of elbow, railway crush of shoulder, and railway crush of arm, leg and trunk, in the third case the arm was removed, with neck of scapula and part of clavicle, and subclavian tied in lower third, operation performed on third day, and death from septicæmia on sixth day Eight disarticulations of the hip gave 4 deaths, 1 died in 20 minutes and 1 in 2 hours, both after gun-shot wounds, and 1 in 4 hours, after railway injury Eighteen disarticulations at knee-joint gave 4 deaths, 1 being an engine crush of both legs, right thigh amputated, 1 of neglect of nurses and secondary hæmorrhage, 1 after operation for necrosis of tibia, and 1 of septicæmia, after secondary hæmorrhage

The tables of resections are interesting, and include some total excisions The most interesting of these operations was a case of removal of the whole eighth dorsal vertebra for crush from the fall of a tree The patient died on the sixth day from a wound of the lung, the paralysis having all gone In reporting the cases many of the operators committed the error of not giving the result as to the subsequent usefulness of the limb Three cases of resection of the sternum in continuity are reported, all for caries, 2½ inches being removed in 1 case All recovered Of the 55 cases of resection of joints 2 died, neither from the operation Of 63 cases of resection of bone in continuity none died

Eighty-four ligations are tabulated, with 11 deaths, these include ligations of the subclavian 4 cases, 2 deaths, 1 from perforation of pleura by aneurismal sac, internal mammary 1, axillary 3, brachial 17, 2 deaths, 1 from secondary hæmorrhage, common carotid 6, 3 deaths, from hæmorrhage on twenty-second day, in 6 hours from exhaustion, and from reopening of sac of returned aneurism and tying external carotid and internal jugular, external carotid 4, 1 death, just mentioned, external iliac 4, 1 death from repeated hæmorrhage, common femoral 2, 2 deaths from recurring hæmorrhage, superficial femoral 10 cases, popliteal 1, and other minor ligations

Under the head of "trephining bones of the cranium" we find 44 observations tabulated, with 8 deaths In 17 cases the operation was performed for recent *depressed* fracture, with death in 2 cases, in 11 cases for epilepsy after fracture or other cranial injury, 1 death, 2 permanent recoveries, improvement in 2 In one case, after old fracture of parietal bone, and epilepsy, there was profound coma, which was relieved by withdrawal of pus, 5 crown-heads were removed, and a spiculum lying on dura, exploration and incision evacuated the abscess, a drainage tube was used for 10 days, hernia cerebri occurred, which was treated by compression by flaps of scalp, recovery was rapid and permanent In one case of depressed fracture from railway injury 27 fragments of bone were removed The patient was comatose for 9 days and then recovered

Of tracheotomy for foreign bodies 43 cases are tabulated, with 4 deaths For disease the operation was performed 69 times with 49 deaths

One hundred and fifteen amputations of the female mamma gave 7 deaths, 6 after operations for cancer, for which the operation was performed 98 times The causes of death after the operations for cancer were general erysipelas 1 case, phthisis 1 case, rapid recurrence 1, congestion of lungs from anæsthetic 1, septicæmia 1, died on table from anæsthetic 1, extension of disease 1 Of the 92 cases which recovered, the result as to permanence is given as complete in 3 cases, no recurrence after 12 years in 1 case, after 9 years in 1, after 7 years in 3, after 6 years in 2, after 5 years in 1, after 3½ years in 1, after 2 years in one, after 1 year in 3, indefinite 11 In one case relapse occurred in the cicatrix after 10 years, recurrence and death in 1 case after 5 years, in 4 cases after 2 years, recurrence 5 times after 3 years, 7 times in 1 year, four cases in 6 months, and in 5 cases at an indefinitely stated period Sarcoma is mentioned twice, and 5 other cases were probably sarcomatous, all of these recovered without recurrence, except one, in which the result is not stated

One case of gastrostomy is reported by Herff, for impermeable stricture of the œsophagus from swallowing concentrated lye Howe's operation, gastrotomy at two periods, was performed The child, 7 years old, regained her health perfectly, was alive 6 years after the operation, strong and well nourished, though always fed through the fistula Herff also gives 2 cases of splenectomy In the first case the spleen was detached from the stomach and lying across the umbilical space Old adhesions to the parietes were detached by the fingers, and about ten vascular adhesions ligated A pedicle of vessels was included in Atlee's clamp The spleen weighed 4½ pounds The maximum temperature reached was 100°, pulse 80, no vomiting The wound healed and the sutures were removed between the fourth and sixth days, and the clamp on the seventh On the same day the woman had an angry altercation with her husband, which was followed by the expulsion of a macerated fœtus, tetanus, and death on the following day In the second case a leukæmic spleen was removed, it filling the whole abdominal cavity and pushing up the diaphragm The organ weighed 13 pounds Death was due to hæmorrhage from the broken short adhesions which could not be tied

Cupples reports a case of operation for carcinoma of the pylorus of more than a year's standing, the patient being extremely emaciated There was rapid recovery from the operation, and great relief to stomach symptoms The patient went 500 miles to his home, and died some weeks afterwards Herff reports a nephrectomy for sarcoma of supra renal capsule and kidney, which was floating, the patient made a perfect recovery

Want of space prevents our making a more complete analysis of this report at this time But one of the objects had in view in noticing this report at such

length was to show that such reports are of great value, another was to show that something good can "come out of Texas" Few can form any idea of the immense labor required in making out such a report, and too much praise cannot be given to the Committee, the chairman of which is Dr George Cupples, of San Antonio

TUBERCULAR LESIONS OF THE LUNGS

The "line of march" of tubercular lesions of the lungs is discussed in a most interesting way by Dr J K Fowler, in the October number of the London *Practitioner* The apical position of the primary lesion has been recognized almost as long as we have had exact information about diseases of the lungs But the path and course of extension of the tubercular inflammation has been little studied In 1882 Dr William Ewarts' excellent Gulstonian Lectures on "Pulmonary Cavities" threw much light on the location and mode of growth of these lesions He showed that cavities at the base of the lungs were very rare, that they occurred at the apex oftenest, in the dorso axillary region a little less frequently, and in the mammary still less frequently, although in about one half of all the cases

Dr Fowler aims especially to point out the order in which the tubercular lesions appear, and the tract along which the infection travels in the lungs He claims that in chronic cases, as a rule, the morbid changes follow a definite path In acute cases exceptional courses of development are common

The primary lesion almost invariably is found in the apex of one or both lungs, or rather about an inch below the true apex This corresponds externally with the supra clavicular fossæ Often, but somewhat less frequently, the primary lesion is so located as to correspond with the first and second interspaces below the outer third of the clavicle The direction of the extension of these primary lesions is backward and downward chiefly

From apical primary lesions the first secondary one is usually at the apex of the lower lobe The latter appears very early, as a rule, often when the primary tubercular nodule is no larger than a cherry The location of this secondary lesion is about one to one and a half inches below the upper and posterior extremity and about the same distance from the posterior border of the lower lobe It tends to spread backward and downward along the line of the interlobular septum, producing a wedge shaped mass of consolidation The location of the lesion corresponds with the inner border of the scapula when it is drawn as far away from the vertebra as possible Further extension towards the base of the lower lobe does not take place by a direct increase of the area of consolidation so much as by the formation of irregularly scattered tubercular nodules The base of the lung is very rarely affected to any extent, and in the majority of cases contains no tubercular material When this is not true the lung tissue has first been weakened by pneumonia, pleurisy or similar affections

The middle lobe of the right side often escapes invasion, and if involved, is not usually until late in the course of the disease The lesion generally is tuberculo pneumonic in character, and follows a primary lesion of the upper lobe of the same side The area of consolidation may be considerable, but the area of softening is generally small

When the opposite upper lobe is secondarily affected, which, as a rule, occurs early, the lesions are located symmetrically in both lungs A third location is noticed in secondary lesions at times This is close to the interlobular system about halfway between its upper and lower extremities, and corresponds on the chest wall to the upper part of the axilla

When the lower lobe of the opposite lung is secondarily affected the lesion is similar to that on the side primarily involved Almost invariably the primary lesion is in the apex of one lung, the next lesion appears in the upper part of the same side, and then a third focus of disease may appear, symmetrically located in the opposite lower lobe Rarely this order is found changed and the lower lobe of the lung primarily affected is untouched by the disease, which appears secondarily in the apex of the lower lobe of the opposite side

Dr Fowler believes that in those cases that illustrate most perfectly the eruption of lesions in the order just sketched, the infection of new lung areas is by means of the secretions carried through the bronchial tubes to the various parts of the lungs. When infection occurs through the agency of the blood the foci of the disease follow no plan as regards place or time of appearing Also when infection of new areas takes place through the lymphatic channels it follows no longer the plan and course described The information given us by Dr Fowler, if confirmed, will enable us to judge more definitely of the stage of advancement of the disease, at least in all chronic cases, and furnishes us also with landmarks which locate the lesions Of the importance of locating the secondary lesion near the upper posterior part of the lower lobe he says "The infiltra-

tion of the lower lobe at this spot in the early stage of phthisis is one of the most constant features in the pathological anatomy of the disease, and its recognition is a matter of much importance, as in doubtful cases it is almost positive proof of the existence of tuberculous disease of the lungs I have seen extensive lesions of the apex not presenting a trace of tubercle in which the lower lobes were quite free from disease The existence of this lesion as a test of the tubercular nature of the disease holds good, I believe, as a positive test, but its absence does not negative tubercle "

CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS

At a meeting of the Executive Committee on October 5, in Philadelphia, nine *Special* Societies were represented by one member from each Society Of the nine representatives present, four were from New York, two from Philadelphia, one from Baltimore, one from St Louis and one from Alabama Dr Wm Pepper was made Chairman and Dr John P Bryson, Secretary The first regular meeting of the Congress is to be held in Washington, D C, September 18, 19 and 20, 1888, the sessions of the *Congress* to be held in the evenings, leaving the day for the Special Societies to meet for their own work separately It is worthy of notice that the American Gynæcological Society, which is one of the largest and most influential of the National organizations of specialists in this country, at its recent meeting in New York refused to join the proposed Congress, and appointed its next annual meeting in Boston, Mass, to commence on the *third* Tuesday of September, 1888 As the entire aggregate membership of the nine cooperating specialist societies does not probably exceed 350, or less than half of 1 per cent of the regular practicing physicians and surgeons in this country, their assumption of the name of "The Congress of American Physicians and Surgeons," will hardly deceive anybody but themselves Neither will the amount of scientific work they will be likely to accomplish in three September evenings at Washington, in addition to two sessions in separate society capacity on the same days, be sufficient to astonish the professional world

THE WESTERN PENNSYLVANIA MEDICAL COLLEGE, Pittsburg, is reported to have commenced its second annual course of instruction with a class of nearly 100 students, which is the more gratifying, as the Faculty recommend a full graded three years' course

WILLIAM SCOVELL SAVORY, F R S, London, has been appointed by the Queen Surgeon Extraordinary to her Majesty, in place of the older Richard Quain, recently deceased

COMPLIMENTARY —We see it stated by cablegram that the Sugar-Coated Pills and Effervescing Salts, furnished by W R Warner & Co, Philadelphia, received the highest award for superior quality from the American Exhibition in London

SOCIETY PROCEEDINGS.

PHILADELPHIA PATHOLOGICAL SOCIETY

Stated Meeting, September 22, 1887

THE PRESIDENT, J C WILSON, M D, IN THE CHAIR

DR W OSLER presented a specimen of

THROMBOSIS OF THE PORTAL VEIN

Chronic obstruction to the blood flow in the branches of the vena portæ within the liver, such as occurs in cirrhosis, is probably the most common cause of this rare condition We not infrequently meet with atheroma in the portal vein and its branches in cirrhosis, one factor in the production of which, as in the pulmonary artery in mitral stenosis, is the heightened blood-pressure, and to this change the thrombus formation is closely related At first, and possibly for a long time, mural, it gradually becomes obliterating, and if the collateral circulation is established, the patient may live some time, as in a case which I reported in 1882 (*Jour Anatomy and Physiology*), in which the vein was represented by a firm fibrous cord The specimen here shown was taken from a Swede, aged about 45, who was admitted to the University Hospital May 7 with ascites As he could not speak English it was difficult to obtain a history, but we ascertained that he had been in failing health for some time, and latterly his abdomen had become swollen It did not appear to have come on suddenly The liver dulness was reduced, the superficial abdominal veins were moderately distinct, and the case was regarded as one of ordinary cirrhosis He was tapped five times between May 20 and July 14, and from 12 to 15 pints of serous fluid removed on every occasion He was able to be up and about after each tapping, but he gradually became emaciated, weak, finally comatose, and he died July 20 There were no hæmorrhages, and it may be stated that the abdominal veins were at no time more distended than is common in atrophic cirrhosis The condition post mortem was as follows fibrous adhesion in peritoneum, atrophic cirrhosis of liver, with thickened capsule, old firm thrombus in vena portæ, extending into splenic and mesenteric veins, thickening and patchy

calcification of the walls of the portal vessels, great enlargement and induration of the spleen, kidneys indurated, no special changes in thoracic organs A careful dissection of the abdominal veins was not made, but I am told by Dr Miall, who made the autopsy, that the peritoneum was very dark and the veins behind the liver very large The collateral channels were, no doubt, largely the anastomoses which exist between the peritoneal, mesenteric and lumbar veins and the gastric, diaphragmatic and œsophageal vessels As in the case of fibroid obliteration referred to, a perfect collateral circulation may be established in occlusion of the portal vein, and the patient may live for months or years In this instance the thrombus was evidently old, as in places there were calcareous changes The branches in the liver were filled with soft clots The gall bladder was full of normal bile In two other cases of cirrhosis I have met with thrombi in the portal vein, in both instances with thickening and atheromatous changes in the vessel walls, but the thrombi had not undergone such degenerative changes as in this specimen

Dr H F Formad presented a specimen of

CHRONIC HYPERTROPHIC CIRRHOSIS OF THE STOMACH WITH GASTRIC ULCER, AND COLLOID CHANGE OF THE MUCOUS MEMBRANE

A sailor, aged 38, a German, was admitted to the Naval Hospital 10 months ago with the symptoms of dyspepsia and occasional vomiting There had been absolutely no pain at any time and no vomiting of blood Three months before death he began to have serious difficulty with swallowing, with œsophageal regurgitation, and though a stricture was sought for none was found Very curiously, for a few days immediately preceding death he swallowed well Death resulted from starvation At the autopsy the abdominal cavity was found to contain 52 ozs of straw colored fluid and showed evidences of old peritoneal inflammation, especially at the upper part, where the organs were matted together into one mass The stomach was quite contracted, having a capacity of 4 to 5 ozs Its walls were ½ to 1 inch thick, the thickness greatest at the cardia and gradually diminishing till within 2 inches of the pylorus, where the wall abruptly resumed its normal condition The first impression given was that it was a case of cancer, but closer examination showed it to be simply great thickening of the wall with polypoid elevations of the mucous membrane and secondary colloid change The ulcer was situated in the posterior wall near the cardia, its bottom formed by tissue in the spleen and the peritoneal coat of the transverse colon Communication with the abdominal cavity had been prevented by firm adhesions The omentum contained a number of colloid granules as large as peas The abdominal lymph glands appeared to be amyloid The case was remarkable, first, in the complication of hypertrophy with gastric ulcer, a condition which the reporter had never before seen, second, in that the hypertrophy should commence at the cardia instead of at the pylorus

Dr Formad also presented the specimen of a

STAB WOUND OF THE ABDOMEN

Laparotomy had been performed and a wound of the intestine found, which was sutured The man died suddenly 60 hours after the operation At the autopsy there was only a very slight amount of peritonitis found and the wound in the intestine had firmly united The abdominal condition not being sufficient to account for death, the brain was examined and a very distinct embolus in the floor of the fourth ventricle found The stomach had not been touched, but on its peritoneal surface were some slight tears, and opposite them in the mucous membrane, but not corresponding exactly with them, were several distinct, small linear ulcers, which appeared like ulcers due to some injury They did not look at all like ordinary ulcers, but still had evidently formed ante mortem There was an old hæmorrhagic infarct of the kidney

Dr Osler had been particularly interested in the first specimen, and had hoped that possibly it might prove to be related to the formation of gastric ulcer in the way pointed out by Dr Baumgarten, and to which he wished to call attention, namely that the movement of the stomach against the costal edges produces distinct localized thickenings, and that in corresponding points of the mucous membrane ulcers form

Dr Formad also presented a specimen of

GUNSHOT WOUND OF THE HEART

The ball had entered the chest between the fourth and fifth ribs on the left, passed through the left ventricle, and was found imbedded in the spinal column Death was instantaneous The principal point of interest lay in the fact that the ball had traversed the cavity of the left ventricle near its base without injuring the chordæ tendineæ or the leaflets of the mitral valve

Dr Wescott presented

A MEDIASTINAL TUMOR,

removed from a man, aged 28, who had entered the University Hospital a week ago He was a brakeman, with good family history and personal habits, and no venereal history He had been in good health and at his work till last July, when dyspnœa developed and he quit work About the same time he noticed a tumor in his neck There was no pain nor difficulty of swallowing On admission he was in a condition of orthopnœa Over the left side of the chest there was complete dulness, extending to the right edge of the sternum, with absence of respiratory murmur The apex beat of the heart could not be seen or felt The tumor of the neck involved the superficial lymph glands and could be traced behind the sterno cleido mastoid muscle and down into the chest There was no inequality of the pupils and no œdema At the autopsy, on opening the chest nothing but a large fleshy mass and the edge of the right lung could be seen The mass penetrated the chest wall between the first and second ribs and became continuous with the tumor in the neck It was closely attached to the bodies of the dorsal vertebræ from the first to the fourth, filled all

the upper part of the left chest, and completely enveloped the great vessels The œsophagus was pushed to one side but not compressed The left lung was completely collapsed and contained numerous secondary nodules The heart was pushed down and back, but was normal The mesenteric glands were enlarged A section of the tumor showed largely fibrous tissue The reporter asked whether, in the case of such a large mass, the absence of pressure symptoms was not remarkable?

DR J B WALKER said that in the absence of pressure symptoms such a large tumor was, in his experience, unique, generally very much smaller ones giving rise to marked symptoms

CHICAGO GYNÆCOLOGICAL SOCIETY

Regular Meeting, Friday, June 24, 1887

THE PRESIDENT, CHAS WARRINGTON EARLE, M D, IN THE CHAIR

DR JOHN BARTLETT read the following paper, entitled *Several Items of Obstetrical Interest*

IS QUININE AN OXYTOCIC?

Some twenty five years ago, as well as my memory serves me, the question began to be mooted whether quinine was an abortifacient and oxytocic or not Prior to 1862, so far as I am aware, preparations of cinchona were given to pregnant women freely and without any suspicion that harm might result therefrom To day the profession is divided in opinion on this subject, some scrupulously withholding quinine from the pregnant woman, others giving it without reserve In the course of my reading, I have chanced upon an observation of Mauriceau's which indicates that two years prior to Sydenham's notice of the bark, this obstetrician had sought an answer to the query in question I quote Obs CCLXXII "On the 28th of October, 1680, I delivered a woman who had during a period of fifteen days three or four violent accessions of tertian ague, which obliged me, after a bleeding from the arm, to administer cinchona By the use of this remedy the fever entirely ceased After having continued in good health for ten or twelve days, she was happily delivered of a large healthy boy This experience caused me to recognize a fact, which has since been confirmed by a number of similar cases, to wit, that pregnant women can take cinchona with the same benefit as other persons, without its occasioning any injury to the mother or child "

I cannot but regard it as a curious and interesting fact that a question as to the specific action of a medicine put forth in 1680 should be *adhuc sub judice*

Last year I reported to this Society a case of

PLACENTA PRÆVIA IN WHICH THE PLACENTAL TISSUE EXTENDED OVER THE ENTIRE OVUM

Cases have been reported by Sirelius, Barnes, Hegar, Hicks, and Judell in which placentæ have been so spread out as to occupy nearly the whole of the internal surface of the uterus In connection with this subject, I call your attention to the following observation of La Motte's

Observation CCCCI—"The 22d of July, 1717, Dr Ducet sent to desire me to go to a farmer's wife, two leagues off, who had been in labor ten days and ten nights, during which time she had not the least rest" (La Motte here proceeds to describe how he delivered by turning and continues) "I had a great deal of trouble in bringing away the placenta, which was not one-third so thick as usual, but merely membranous, of about the thickness of a child's diaphragm, it not only adhered to the bottom of the uterus, but to its whole circumference, so that a young practitioner would hardly have believed that any placenta at all was left behind"

PLACENTA PRÆVIA WITH CERVICAL ATTACHMENT

In Charpentier's treatise on obstetrics, we find the following list of authors who admit that in certain cases of placenta prævia it is possible that the placenta find attachment within the neck of the uterus Sirelius, Barnes, Thudicum, Chavanne, Marchal, Thévenot, Keppler, Pajusko, Rokitansky, Sackreuter, Mettenheimer, La Chapelle, Pinard, Tarnier, Hubert, and Noel

I desire to prefix to this list the name of Andre Levret From his work, "L'Art des Accouchmens," I extract the following passage from his paper on Placenta Prævia published at Paris in 1751 Page 373 "An interesting question naturally arises in this connection, Why some women having the placenta adherent in the neck proper of the uterus arrive at term, whilst others, by far the majority, under the same condition do not reach the normal limit of gestation?

"This variation in effects proceeding from the same cause must depend upon some particular circumstance as a determinating clause I explain the matter in this way According as the placenta is primarily attached higher or lower in the neck proper of the uterus, hæmorrhage will occur sooner or later Thus when that vascular mass has taken root nearer to the os tincæ, the woman will be able to approach nearer to the term of gestation than if it had been implanted as high as the constriction (internal orifice) of the uterine neck And thus the time of interruption of the pregnancy by bleeding will vary with the level of attachment of the placenta between the two extremities of the neck It is demonstrated as well by the mechanism of pregnancy as by the daily experience of the accoucher, that the neck does not begin to expand to aid in augmenting the capacity of the uterus except in the later months of gestation, and that it is by segment that the cervix continues thereafter to expand from above downwards Now, the neck cannot thus expand without sooner or later obliging the placenta, which is not susceptible of like expansion, to detach itself in part, either in some point of its circumference if it be more advanced upward on one side than on the other, or at its centre if this be in exact correspondence with the upper end of the cervical canal It follows then as a necessity that a hæmorrhage shall occur at a time more or less near or more or less distant from the natural term of pregnancy, according as the placenta shall be at-

tached further from or nearer to the [lower orifice of the] central canal

The credit of first suggesting

ABDOMINAL SECTION IN THE TREATMENT OF RUPTURED OF THE CYST IN ABDOMINAL PREGNANCY

is generally given to Osiander and Heim In Levret's work on obstetrics may be found the following sentences His appreciation of the difficulty incident to the detachment of the placenta in such a case is complimentary to his foresight and sagacity

"In extra uterine pregnancy, the fetus inclosed in the Fallopian tube or ovary ordinarily bursts its envelopes before full term, and the mother perishes of hæmorrhage with her infant in her abdomen This sad accident seems to indicate abdominal section, but I doubt very much whether an operation would succeed in saving the mother even if there were present sufficient symptoms to enable one to decide, and to decide promptly, upon an operation Because, it would be necessary, in order to hope for success, that the site of attachment of the placenta should have power, such as the womb has to contract very powerfully and quickly, and that is an impossibility"

DO DIRECT-TRACTION FORCEPS EXERT DANGEROUS COMPRESSION?

Some writer has said that, after inventing an instrument, the first thing that one meets is an objection It is objected to the Tarnier direct traction forceps that the screw by which the handles are approximated so as to take hold of the head may exercise a dangerous compression My object in this communication is to show that such compression need not be made, and that the screw does not therefore constitute an objection to the instrument

I beg leave here to quote from Dr Barnes He says "Let us study the power of the forceps How does it take hold? You may at first sight suppose that this is accomplished by grasping the handles The hold, especially in short handled forceps, cannot be due to the handles It is really due to the curvature of the blades, which fit more or less accurately upon the globular head, and the compression of the bows of the blades against the soft parts of the mother, supported by the bony ring of the pelvis In many cases, this outward pressure upon the bows of the blades is enough to serve for traction It is not necessary to tie the handles of the forceps You may even do without handles altogether

For a few years past I have used the direct traction principle in almost all cases of forceps delivery And I have found that my hold upon the common handles becomes more and more slight as experience enlarges So that in an ordinary case of delivery, the fingers of the left hand rest upon the handles rather to ascertain whether compression be needed than to press the handles together

Recently I have witnessed two cases of delivery as an assistant to Dr J H Hooper, who uses forceps provided with direct traction handles I was surprised to find that he frequently let go of the ordinary handles entirely and while he pulled upon the traction handle with one hand, he used the other to determine the progress of the head, or to sustain the perineum Upon inquiry I learned of Dr Hooper that he did *not* ordinarily clasp the handles, only when powerful traction was applied did he deem it necessary to do so I think it may be said that such compression as may be needed may be employed to the ordinary handles of a direct tractor by means of a screw or otherwise, without fear of injury to the child

THE VERNIX CASEOSA, AN ELEMENT OF ERROR IN THE DIAGNOSIS OF THE CHARACTER OF PUERPERAL HÆMORRHAGE

Several months since, I was called to a woman pregnant with her eighth child at full term Six hours prior to this visit, without exciting cause, there had been so great a flowing as to demand the use of the tampon The os uteri was then closed, there had been no pains until the last half an hour I found the pains active, and hæmorrhage free, and increased during uterine contractions The os uteri was two centimetres in diameter and softened, through it could be recognized the globular form of the head Between the presenting part and the finger could be plainly felt a thick plate of tissue firmer than a clot, and of the consistence of a placenta Over its surface could be traced depressed sulci, districting the mass into lobuli No doubt was entertained as to the nature of the case I had never met with an instance in which the diagnosis of placenta prævia was so speedy and so positive Assistance was immediately sent for I was disturbed in the hurried preparation for such interference as more thorough examination might suggest, by the cry of the patient that a great quantity of blood had passed away The membranes had ruptured, the bleeding had ceased, the "placenta" had disappeared, and the head was passing the perineum

After the birth of the child, I looked about the site of the *res gestæ* for an explanation of the deceptive feel, so simulating that of the placenta I found that the entire vertex had been covered by a disc of vernix caseosa, one third of an inch in thickness, of the appearance and consistence of leaf fat In the presence of Dr Clark, I placed side by side the maternal surface of the placenta and the disc of the vernix caseosa, the feel of the two was very similar Dr Clark had never encountered such an instance of superabundant vernix The upper parts of the arms of the child were so bedaubed with the sebaceous secretion as to remind one of the appearance of the spokes of a wheel on a muddy road The hæmorrhage came from a surface of detached placenta situated about an inch from the os uteri

DR E W SAWYER The great objection that Levret raised to laparotomy was the management of the placenta. He thought the hæmorrhage would necessarily be fatal, because there is no provision made by nature for the contraction and closure of the large vessels Thomas has enlightened the world greatly on that point, showing how the placenta should be managed Dr Janvrin, of New York, speaks of a case of extra-uterine pregnancy, with the head presenting so low that he was tempted to draw

the upper part of the left chest, and completely enveloped the great vessels The œsophagus was pushed to one side but not compressed The left lung was completely collapsed and contained numerous secondary nodules The heart was pushed down and back, but was normal The mesenteric glands were enlarged A section of the tumor showed largely fibrous tissue The reporter asked whether, in the case of such a large mass, the absence of pressure symptoms was not remarkable?

DR J B WALKER said that in the absence of pressure symptoms such a large tumor was, in his experience, unique, generally very much smaller ones giving rise to marked symptoms

CHICAGO GYNÆCOLOGICAL SOCIETY

Regular Meeting, Friday, June 24, 1887

THE PRESIDENT, CHAS WARRINGTON EARLE, M D, IN THE CHAIR

DR JOHN BARLEEN read the following paper, entitled *Several Items of Obstetrical Interest*

IS QUININE AN OXYTOCIC?

Some twenty five years ago, as well as my memory serves me, the question began to be mooted whether quinine was an abortifacient and oxytocic or not Prior to 1862, so far as I am aware, preparations of cinchona were given to pregnant women freely and without any suspicion that harm might result therefrom To day the profession is divided in opinion on this subject, some scrupulously withholding quinine from the pregnant woman, others giving it without reserve In the course of my reading, I have chanced upon an observation of Mauriceau's which indicates that two years prior to Sydenham's notice of the bark, this obstetrician had sought an answer to the query in question I quote Obs CCLXXII "On the 28th of October, 1680, I delivered a woman who had during a period of fifteen days three or four violent accessions of tertian ague, which obliged me, after a bleeding from the arm, to administer cinchona By the use of this remedy the fever entirely ceased After having continued in good health for ten or twelve days, she was happily delivered of a large healthy boy This experience caused me to recognize a fact, which has since been confirmed by a number of similar cases, to wit, that pregnant women can take cinchona with the same benefit as other persons, without its occasioning any injury to the mother or child "

I cannot but regard it as a curious and interesting fact that a question as to the specific action of a medicine put forth in 1680 should be *adhuc sub judice*

Last year I reported to this Society a case of

PLACENTA PRÆVIA IN WHICH THE PLACENTAL TISSUE EXTENDED OVER THE ENTIRE OVUM

Cases have been reported by Sirelius, Barnes, Hegar, Hicks, and Judell in which placentæ have been so spread out as to occupy nearly the whole of the internal surface of the uterus In connection with this subject, I call your attention to the following observation of La Motte's

Observation CCCCI—"The 22d of July, 1717, Dr Ducet sent to desire me to go to a farmer's wife, two leagues off, who had been in labor ten days and ten nights, during which time she had not the least rest" (La Motte here proceeds to describe how he delivered by turning and continues) "I had a great deal of trouble in bringing away the placenta, which was not one-third so thick as usual, but merely membranous, of about the thickness of a child's diaphragm, it not only adhered to the bottom of the uterus, but to its whole circumference, so that a young practitioner would hardly have believed that any placenta at all was left behind "

PLACENTA PRÆVIA WITH CERVICAL ATTACHMENT

In Charpentier's treatise on obstetrics, we find the following list of authors who admit that in certain cases of placenta prævia it is possible that the placenta find attachment within the neck of the uterus Sirelius, Barnes, Thudicum, Chavanne, Marchal, Thévenot, Keppler, Pajusko, Rokitansky, Sackreuter, Mettenheimer, La Chapelle, Pinard, Tarnier, Hubert, and Noel

I desire to prefix to this list the name of Andre Levret From his work, "L'Art des Accouchmens," I extract the following passage from his paper on Placenta Prævia published at Paris in 1751 Page 373 "An interesting question naturally arises in this connection, Why some women having the placenta adherent in the neck proper of the uterus arrive at term, whilst others, by far the majority, under the same condition do not reach the normal limit of gestation?

"This variation in effects proceeding from the same cause must depend upon some particular circumstance as a determinating clause I explain the matter in this way According as the placenta is primarily attached higher or lower in the neck proper of the uterus, hæmorrhage will occur sooner or later Thus when that vascular mass has taken root nearer to the os tincæ, the woman will be able to approach nearer to the term of gestation than if it had been implanted as high as the constriction (internal orifice) of the uterine neck And thus the time of interruption of the pregnancy by bleeding will vary with the level of attachment of the placenta between the two extremities of the neck It is demonstrated as well by the mechanism of pregnancy as by the daily experience of the accoucher, that the neck does not begin to expand to aid in augmenting the capacity of the uterus except in the later months of gestation, and that it is by segment that the cervix continues thereafter to expand from above downwards Now, the neck cannot thus expand without sooner or later obliging the placenta, which is not susceptible of like expansion, to detach itself in part, either in some point of its circumference if it be more advanced upward on one side than on the other, or at its centre if this be in exact correspondence with the upper end of the cervical canal It follows then as a necessity that a hæmorrhage shall occur at a time more or less near or more or less distant from the natural term of pregnancy, according as the placenta shall be at-

as usual This arrangement is so that when the bed is folded on itself all the ordinary obstetrical operations can be performed with ease, as the bed is now the heighth and length of the usual operating table A woman is brought into the lying in chamber when the os uteri is well dilated, if she is a primipara, if a multipara she is brought in somewhat earlier If time is permitted, she has a carbolic acid bath before being brought into the lying in room The bed clothes are used only once During the early stages the woman is left to do about as she pleases, but no unnecessary examinations are made and *never* until the hands are thoroughly disinfected A vaginal injection is given about the time the head begins to press against the perineum, and as soon as the vulva begins to open the spray is turned on to the parts and kept constantly going until after the completion of the third stage During the latter part of the confinement the attending physician is busy making all manner of measurements of the abdomen and pelvis He also listens carefully to the fœtal heart sounds, from which he decides in regard to the advisability of hastening the labor The placenta is always expressed, and the fingers or hands never passed into the vulva unless absolutely necessary

The immediately delivery, with all its details, is done by a midwife, and no pulling or tugging or dilating of the os or perineum is attempted at any time The parts are frequently washed, and the occiput made to hug the pubic arch by pressing the head up, the tissues of the perineum being between the hand and the head

If a rupture is threatened, the parts are supported by the extended hand and the edge reinforced, if I may use the term, by drawing down more tissues The cord of the child is tied by passing around it a little rubber tape, and the child is removed from its mother to be weighed, then washed, and measured in every part of its little body, length, breadth and thickness, head, thorax, pelvis and legs But very little, if any, ergot is given to the mother, and in the course of a few hours she may be seen in the general ward, with her baby in a little cot by her side

The operating room in this hospital is about fifty feet square The temperature is raised from 80° to 100° F, and for twenty four hours previous to a large operation sulphur is burning in the room All clothes and linen to be used about the patient are fumigated and placed in closed baskets Instruments are boiled in a ten per cent solution of carbolic acid and then soaked in a seven per cent solution Inside of the raised seats is the operating table The floor is of stone Upon one side is a pile of disinfected linen Next to it, a table containing hæmostatics, next, one upon which all kinds of restoratives are placed, with a hypodermic syringe filled with brandy or ether ready for use In a remote corner is a receptacle to receive all soiled clothes Upon the other side of the operating table are all the instruments in trays, and a battery for emergencies is in a convenient position At one end of the room are two or three places for washing, around which the director of the clinic and his assistants are seen for some time previous to the operation scrubbing their arms and hands and cleaning their nails Two or three instruments for spraying are placed in an appropriate position, and are worked during the entire operation It was here that I saw

A CÆSAREAN SECTION IN WHICH BOTH MOTHER AND CHILD WERE SAVED

The operation was delayed until the *os uteri* was fairly dilated The operating room had been thoroughly prepared and the woman properly disinfected An anæsthetic was given and the abdomen repeatedly disinfected, even the hairs along the median line being plucked out The incisions through the abdominal walls were the usual ones, the only additional procedure being that a thread was passed through the tissues at the upper and lower end of the abdominal opening The peritoneal covering of the uterus was incised and dissected back about one-third of an inch, so that a small piece of the uterine wall could be removed and the peritoneum folded over the end The position of the placenta was carefully ascertained and an opening made into the membranes surrounding the child, and the feet seized and the child extracted It was given at once to a nurse for resuscitation, who shook it violently, its head hanging downwards The placenta was now taken out of the uterine cavity, and carbolized water was used in great quantities The incision through the walls of the uterus was very carefully closed with interrupted sutures, then a layer less widely separated, and to keep this secure the chief midwife sewed over and over with catgut sutures the peritoneum until it seemed absolutely impossible for anything to get into the abdominal cavity from the uterus or from the abdominal cavity into the uterus The external wound was closed by the usual method Neither cotton batting nor any other of the usual dressings were applied on the outside, but a flat bag of shot, weighing from two to six pounds, was laid on the abdomen Drainage through the vagina ice, over the hypogastrium, the woman made a good recovery

I had the opportunity of examining this woman's pelvis a few days before the operation I could feel very plainly the promontory of the sacrum, and should judge that the conjugate was about two and one-half inches The os was dilated to the size of a half dollar and craniotomy could have been well performed, but Chiara was intent on trying to save not only the mother's, but also the child's life He succeeded in doing both

None of the grave complications which are dreaded were present in this case The hæmorrhage after the incision through the uterine peritoneum was very slight, and after the extraction of the child only a moderate amount of blood was lost After the wound in the uterus was closed, friction was made over the organ till it was firmly contracted, the abdominal opening was then closed as I have stated My notes do not state whether or not a rubber cord was placed around the uterus at the supra-vaginal junction

EXTIRPATION OF THE SPLEEN

This abdominal tumor was supposed to be ovar-

ian Usually a diagnosis is made by tapping and the fluid examined by the microscope, but in this case the precaution was not taken Upon opening the abdomen, the tumor was found to be a cyst of the spleen filled with echinococci These were thoroughly scraped out, the cavity cleansed, and the edges of the cyst stitched to the abdominal walls A glass drain was placed at the bottom of the wound, and it was thoroughly washed out with bichloride and dressed with iodoform, and the woman made a good recovery

(*To be concluded*)

PHILADELPHIA COUNTY MEDICAL SOCIETY

Stated Meeting, October 12, 1887

THE PRESIDENT, J SOLIS-COHEN, M D, IN THE CHAIR

DR CARL SEILER read a paper on

CHRONIC RHINITIS AS AN ETIOLOGICAL FACTOR OF ACNE OF THE FACE

For a number of years I have made the observation that acne vulgaris and acne rosacea co existed frequently with chronic rhinitis, and particularly with the atrophic form of nasal catarrh, but it is only lately that I have come to the conclusion that this form of nasal disease is in many cases of acne the exciting cause This conclusion may seem far-fetched and perhaps unreasonable at first glance, but I hope to be able to show that there is undoubtedly a close connection between the two affections For this purpose I will give a short history of a few of the cases which have come under my observation, before entering upon a theoretical discussion of the connection between chronic rhinitis and acne

Case 1—J H, aged 38 years, a broker by profession, consulted me for chronic nasal catarrh He stated that he had suffered from stoppage of the nose for several years, and that every morning he blew out large scabs After this his nose felt clear but dry, and he had lost the sense of smell to a very large degree For two or three years he had noticed a redness of the external integument of the nose, which had become gradually worse, so that at the time I saw him it had spread from the nose to the cheeks, and pimples had made their appearance The rest of his face was free from pimples or redness On inquiry as to his habits, he said that he had always been a total abstainer from alcohol in any form, and the redness of his nose was the more annoying to him, as it gave rise to jocose remarks on the part of his friends His general health was good, and there were no symptoms of gastric disturbance

On examination, I found the anterior nasal chambers filled with dry scabs of hardened mucus, and having removed them, saw the mucous membrane below them was unusually pale, both on the septum and over the turbinated bones The lower turbinated bone was barely projecting from the wall of the nose, and the turbinated cavernous tissue apparently absent, as no impression could be made by pressure with the probe This condition caused the anterior chambers to be abnormally large, so that the posterior wall of the naso pharynx could easily be illuminated and viewed through the nostrils Irritation with the probe produced but a very slight amount of moisture to gather around the spot touched, while the whole of the mucous membrane was abnormally dry There was no odor

The treatment consisted in cleansing the nasal cavities morning and night with an alkaline wash, and in stimulating the mucous membrane with dilute nitrate of silver in powder, a small quantity of which was blown into the nostrils two or three times a week In order to keep up the stimulation a tampon of cotton was introduced into the anterior nasal chambers placed against the side of the nose, in place of the atrophied inferior turbinated bone, which tampon was renewed by the patient after the cleansing morning and night As an application to the skin I prescribed a lotion consisting of alcohol and precipitated sulphur, to be applied every night with a tuft of cotton, and to be washed off in the morning with soap and water

Under this treatment the acne gradually diminished, and the mucous membrane of the nose became again bathed with secretion, until after a little over three months the redness had entirely disappeared, and the cotton tampons could be dispensed with, because the lower turbinated bones, or at least the cavernous tissue, began again to project into the lumen of the anterior nasal chambers I saw the patient again three years later, unfortunately without having an opportunity of examining his nose, but he told me that there had been no return of the acne, and that his nose troubled him but little, and then only when he neglected to use the alkaline wash, the sense of smell had also returned to a large degree, but was not as acute as he might wish

Case 2—A L, aged 20 years, machinist, from Wilmington, had had scarlet fever when 10 years old, and since then had suffered from nasal catarrh At about the age of puberty pimples began to appear on his face, which gradually became larger and more numerous, until, when I saw him, his face and even neck were covered with various sized pustules in different stages of development In the free spaces between them comedones were numerous, and at the angles of the jaw and on the neck were large scars, forming pockets in some instances, caused by confluent acne pustules His general health was good On examination, I found practically the same condition of things as in *Case 1*, except that a disagreeable odor was present, and a perforation of the septum existed This latter circumstance led me to inquire for syphilitic infection, but I could not elicit anything pointing to the existence of even a taint, but found that he had been in the habit of picking off the scabs of hardened mucus from the lower portion of the septum with his fingernail, and had thus gradually scratched a hole into the cartilaginous partition

Having at that time a suspicion of the connection

between atrophic rhinitis and acne, I directed, for the sake of experiment, the treatment solely to the nasal chambers, and intentionally made no applications to the acne pustules The treatment in other respects was the same as that adopted in *Case 1* On account of the distance of the patient's home from the city, I saw him but seldom, and it was several months before much improvement was noticed However, in the course of about eighteen months the acne had disappeared entirely, as had also the comedones, and the chronic rhinitis had so far yielded to the treatment that the patient considered himself cured

Case 3 —Miss E S , aged 22 years, school teacher, general health moderately good, has felt a stoppage of the right nostril for some years, while the left nasal chamber was free but very dry, so that she had to use cosmoline or cold cream every night before she felt at all comfortable In the morning she occasionally expelled a small scab of dried mucus of a yellowish green color On her face were numerous pimples and comedones, but distributed more largely on the left side When asked, she stated that the pimples had made their appearance two or three years ago, had always been more numerous on the left side of her face, and did not seem to have anything to do with her diet, as she had, at the advice of her physician, abstained from various articles of food for considerable periods of time, without apparently producing any effect upon the acne Her monthly periods did not seem to her to produce any increase in the number of the pimples

An examination of the nose proved this to be one of those cases which are occasionally met with, in which we find an atrophic condition on one side coexisting with a hypertrophy of the turbinated cavernous tissue on the other The left nasal chamber being abnormally large, its mucous membrane pale and dry, and the lower turbinated bone hardly visible, presented the same characteristics as described above, and for this condition the same treatment was adopted, viz , stimulation with nitrate of silver and powder, and the cotton tampon after the dried secretion had been removed The other nasal chamber presented the well-known features of the hypertrophic nasal catarrh, with its injected mucous membrane, from which a copious flow of secretion is poured at the slightest irritation, its projecting turbinated tissue which obstructs the lumen of the lower meatus, and its frequent projections, from the septum Here an entirely different treatment had to be adopted, which it is needless to describe here in detail, in fact, the two sides of the nose were treated as though they were two separate and distinct cases, the one an atrophic, and the other one of hypertrophic rhinitis The sulphur and alcoholic lotion was used in this case, as it was important to the patient to get rid of the acne as soon as possible, which happy result was accomplished in a remarkably short time, to her great delight

The above short notes of three cases will, I think, suffice to show that there is a connection between atrophic rhinitis and acne of the face Although a large number of such cases could be cited to demonstrate still further this point, I think it would be waste of time to do so, as they are all more or less a repetition of each other

According to the statements of the different authors on skin diseases, acne occurs with equal frequency in both sexes, and usually makes its appearance at the time of puberty, and is frequent until the age of 30 As predisposing causes are mentioned, gastric disturbances, either lack of or excess of sexual connection, onanism, insomnia, and intemperance, but no mention is made, in any of the works to which I have had access, of atrophic rhinitis as a predisposing or existing cause That the sexual organs have a great influence upon the production of the disease cannot be doubted, for many cases are cited in which acne showed itself only during pregnancy, or at the menstrual period, in women, and it disappears with the cessation of the practice of self abuse in boys and men, also, the fact that it is most frequent at puberty, would point in that direction Some authors lay so much stress upon this that they direct their treatment altogether to the sexual organs, by passing a bougie into the male urethra, and prescribing vaginal douches and medication, having no faith in local applications to the skin of the face

Speaking of the pathology of acne Veiel says "The cause of the inflammation is the mechanical irritation by the inspissated secretion, the latter again is due to deficient glandular activity, because, owing to the defective elaboration of sebum, the secretion has time to dry in the efferent duct " Berend explains the new formation of acne efflorescence by assuming that the swelling of the inflammatory areola around the acne pustules and nodules, occludes the efferent channels of neighboring glands Similar views as to the pathology of the disease are expressed by others It would seem, therefore, that two factors must act in conjunction with each other to produce acne, the one to act as an obstruction to the efferent channel of the sebaceous glands by the introduction of dirt into it, and the drying of the secretion behind it, producing the so called comedones, and also a diminution in the activity of the gland itself, which causes an alteration in the consistence and quantity of the secretion, which thus is not able to remove the foreign body in the mouth of the duct by pressure from behind, as undoubtedly occurs in the healthy skin Thus the retention and accumulation of the secretion causes by pressure a localized inflammation, which is finally relieved by the formation and evacuation of pus In acne rosacea, the rarer form of the disease, we find no formation of pustules, but simply a general more or less diffused inflammation, which is probably due also to a perverted action of the sebaceous glands, but does not lead to a retention of the secretion

I have not been able to find an opinion expressed in any of the books as to the direct cause of the glandular irritation, whether it is altogether local, and caused by obstruction of the duct in the formation of comedones, or whether it is due to reflex nervous irritation, or finally is produced by a more

or less general disturbance of the capillary circulation in the skin of the face The first of these propositions may be at once set down as insufficient to explain the pathological condition, for comedones are frequent in almost every face without being necessarily accompanied by acne The other two propositions may be considered together, for we cannot have inflammation without disturbance of the circulation, and no disturbance of the circulation without nerve influence

The above cited predisposing causes clearly indicate that an irritation of the nervous system must exist somewhere, be it in the mucous membrane of the stomach or in the sexual apparatus, which, by reflex, acts upon the easily influenced capillary circulation of the skin of the face and neck, and thus by causing a change in the capillaries around the sebaceous glands causes a perverted action of these glands if it is kept up for any length of time, or if no relief from blood-pressure is afforded It is my belief that the cavernous tissue covering the turbinated bones provide such a relief, and that this is one of the functions of the erectile tissues of the body This belief is strengthened by the fact that under mental excitement which causes blushing of the face, the cavernous tissue in the nose swells up, while on the contrary, any emotion which causes paling of the face, the erectile tissue of the turbinated bones becomes paler, and diminishes markedly in bulk, facts well known to every laryngologist Let this cavernous tissue be absent, or greatly diminished, as is the case in atrophic rhinitis, and very little or no relief is afforded for the excessive blood pressure in the capillary circulation in the skin of the face, and the result will be acne if any of the predisposing causes be present In the cases above cited, and in many others under my observation, the acne disappeared *pari passu* with the reformation of the cavernous tissue, and thus these would seem to be of some importance as clinical proofs of this theory

I am fully aware that a single line of cases observed by one observer, are by no means a sufficient guarantee for the acceptance of a theory, and it will require many more cases observed by many ob servers, to prove or disprove it At the same time I cannot but think that atrophic rhinitis may be one of the etiological factors of acne

DR C M SELTZER said I wish that the author had been more explicit with reference to the dietetic treatment of these cases I infer from his remarks that the majority of his patients have been underfed Most of the cases that I have observed have had an excess of nitrogenous articles, with a lack of sufficient vegetable food I have obtained the best results by limiting the quantity of nitrogenous food, especially in children, and by increasing the quantity of butter, cream, and fatty articles I give light suppers, secure abundant sleep, and moderate exercise, especially in gymnastics Treated in this way, but little medicine is required

(FROM OUR OWN CORRESPONDENT)

Sixth International Congress for Hygiene and Demography in Vienna

The opening ceremony as well as the first general meeting in connection with the Sixth International Congress for Hygiene and Demography was held in our metropolis on the 26th of September, at 11 o'clock A M , in the nicely decorated "Musikvereins saal " Among the distinguished *savants* who were present there were specially to be noticed Virchow, of Berlin, Brouardel, of Paris, Pettenkofer, of Munich, Spencer Wells, of London, etc The Patron of the Congress, Crown Prince Rudolphus, opened the Congress, which was then addressed by its President, Prof Ludwig He emphasized in his eloquent speech the progress which hygiene had made of late years, as only ten years had elapsed since the International Health Congress of Brussels, the Congresses at Paris, Turin, Geneva, the Hague and Vienna rapidly succeeded The fact that numerous distinguished scholars from almost all the civilized countries of the world had gathered with the purpose of partaking in the deliberations of the Congress was a proof of the recognition of the high importance of this science, a matter which naturally could be easily understood, as hygiene and demography had made it their task to protect mankind against the social evils which, particularly in our century, threatened them to so high a degree His Imperial Highness had given the Congress a special importance and facilitated its work to a great extent, and taking into consideration the preparatory works of the present Congress, and especially the high scientific position of many of the persons who took part in it, we had every reason to entertain the hope that its works would be crowned with much success

The Crown Prince said he considered it an honor and a pleasure to have charged himself with the patronage of the Sixth International Congress for Hygiene and Demography The most precious capital of the State and society was man, each human being represented a certain value, and to preserve man intact for his whole life was not only a command of humanity, but also the duty of all the communities in their proper interest The participation of so many illustrious persons of all nations and from all countries in the present meeting was an evidence of the vast international importance of hygiene, and he was much satisfied to be able to salute them in this city, which was a centre of lively scientific work and earnest investigation

After Dr Kohler, Director of the German Sanitary Board, and Prof Brouardel, of Paris, had saluted the Crown Prince and the Congress in the name of the countries they represented, the eminent French scholar delivered his lecture on the different modes of the spread of typhoid fever, which contained numerous features of a great interest and a high importance He successively discussed the different vehicles of the typhoid germ, and treated the influence of the drink-

ing water and the air on the spread of typhoid epidemics at full length There was no doubt that the drinking water played the chief part in the spread of epidemics of typoid fever, and ninety cases out of a hundred were due to this way of propagation This influence of the drinking water was a fact beyond any doubt, and confirmed by innumerable direct observations as well as by the results of the bacteriological researches Among the various examples of direct observation which the author cites for proving the correctness of his assertions, he refers also to the conditions of the water supply of Paris The water which supplies this city is furnished by different springs The Dhuys and the Panne supply the city of Paris with excellent water, but, at certain times, the Marne, the Seine and the canal of Ourcq must be resorted to, owing to the want of a sufficient quantity of water for the city There is, however, a great difference as to the salubrity of the water which is supplied by the Dhuys and the Panne on one side, and that of the now mentioned rivers on the other side, as these are usually polluted by the dejections of those who live near the rivers and by the seamen The consequences of the use of these different waters in regard to the propagation of typhoid fever became evident in 1886, when, on the 20th of July, they began to use in Paris the auxiliary water supply, owing to the insufficiency of the regular one During the week of July 18–24, 40 persons affected with typhoid fever had been admitted into the hospitals of Paris, from August 1–7 the number increased, and reached 150 When the auxiliary water-supply was discontinued, on August 7, the number of persons affected with typhoid fever rapidly decreased, and from the 15th to the 21st of August only 80 such patients were admitted into the hospitals

The following example was still more striking Dr Régnier, of Paris, had noted the rate of mortality for the year of 1882, in the different caserns of Paris, and could state with all certainty that the new and well constructed casern of Château Landon presented a percentage of mortality (typhoid fever) which amounted to 17 per cent The soldiers of this casern had drunk water which derived its origin from the Marne and which was not filtered In the old casern of Jean Jacques Rousseau, however, the soldiers had drunk water which had been furnished by the Panne, and the mortality amounted here to $\frac{1}{10}$ per cent For 1886, in the casern of Château-Landon, the water of the Marne was substituted for that of the Dhuys, and the mortality of typhoid fever sank, and amounted only to 2 per cent Only two caserns of Paris were still subjected to typhoid fever epidemics, viz those supplied with the water of the Seine

In discussing the results of the bacteriological investigations as to the influence of the drinking water on typhoid epidemics, Prof Brouardel remarked that after the bacillus of typhoid fever had been discovered by Eberth, this microorganism was found in all cases in which persons had been affected with this disease, and missed in all those cases where no typhoid affection was present This fact had also been confirmed by Koch, Gaffky, Cornil, Babès and other investigators, and there was at present no doubt, either from our direct observations or from the results obtained in the microbiological researches, that the drinking-water was really, and in most of cases, the agent for the propagation of the disease under consideration The air which we breathed was also a vehicle for the spread of the typhoid fever, as became evident from the numerous striking examples which the distinguished French hygienist quoted in this direction, and as to the propagation of the disease by means of the polluted dresses or the hands of the nurses, he did not wish to insist upon this fact, as it was known to all of us, this influence, however, had the least importance of all In hygiene, concluded Prof Brouardel, we ought also to have the courage of deriving practical conclusions from the scientific facts, and taking into account the fact that out of 100 patients affected with typhoid fever, 90 suffered from this disease owing to the use of infected drinking water, our duty was to supply our whole population with clean and sound water, which was easier for us than if we were to prevent the air from licking up the infected dejections

Prof Pettenkofer, of Munich, insisted, in a lecture which was received with much applause, upon the necessity of the teaching of hygiene in the universities and the technical schools There were chiefly three classes or professions which had to cultivate hygiene, viz in the first place the physicians, and besides them, the architects and the engineers, the officers of the public administration, however, had also to recommend an hygienic education The more these classes will be instructed in hygienic questions, the more everything practical would be done for the welfare of mankind The lecturer often alluded to the English conditions, and mentioned, among other things, that what the English called "comfort" had an hygienic importance and was worth being imitated In the seventeenth century, when London had not yet a million of inhabitants, the average mortality was 49 per mille, whereas now, though more than four millions of people were living in the city, its mortality was only 21 per mille, a fact which was due only to the hygienic measures which had been taken by the English and which were strictly observed During the war in the Crimea, 95,240 French soldiers out of 309,000 who had gone into the war, died—almost the third part of the army, out of this number, 20,000 died from their wounds, whereas 75,000—almost four times as many—succumbed to various diseases, without having been wounded It was shown that the English had no better lot, the war in the Crimea, however, had caused the English hygienist, Parkes, who had taken part in the whole campaign, as a military physician, to give the hygiene an official position in the administration of the army, and it was on his proposal that the Army Medical School at Netley was created, in which hygiene formed an important part of the curriculum The other States followed the same example, and fifteen years after the war in the Crimea, in the Franco German war, the valuable results of these measures could clearly be observed The total losses of the German armies during that war were 40,888,

out of these 28,282 died from wounds, 346 from other accidents, and 12,282 from various diseases Whereas in the war of the Crimea, the proportion of the losses in the army which were due to the arms of the enemy, in comparison with those due to diseases, was 100 375, the proportion in the Franco-German war was 100 43, *i e*, eight times the more favorable This difference in the mortality, said Prof Pettenkofer, was chiefly due to the hygienic conditions which were adopted in the army, by which numerous cases of abdominal typhoid fever and dysentery were avoided

The sessions of the four hygienic Sections and of the demographic Section began on the next day, and lasted a whole week The most important of the reports and discussions were those bearing on cholera, rabies, and anthrax

Professor Billroth has fully recovered from his late illness, and has begun his course of lectures in the General Hospital L L

MISCELLANEOUS.

THE AMERICAN ASSOCIATION FOR THE CURE OF INEBRIETY will hold its Semi Annual Meeting at the Turkish Bath Hotel, Columbia Heights, Brooklyn, N Y , Nov 9, at 12 M The following is a list of the papers and addresses to be read The President's Address on "The Responsibility of the Inebriate," will be delivered by Dr Joseph Parrish, Burlington, N J , "Report of the Colonial Congress on Inebriety," in London, England, by Dr T Crothers, Hartford, Conn , "The Pathology of Inebriety," by Dr Norman Kerr, London, England, "The Physiology of the Drink Impulse," by Dr J T Searcy, Tuscaloosa, Ala , "Cocaine Toxemia," by Dr J B Mattison, Brooklyn, N Y , "The Power of Alcoholic Influence," by Dr T L Wright, Bellefontaine, Ohio, "Turkish Baths in Inebriety," by Dr C H Sheperd, Brooklyn, N Y , Hygiene in the Treatment of Inebriety," by Dr Albert Day, *Boston, Mass* , "Report on Asylums for Inebriety in New Zealand and Australia," by Dr D McGregor, *Gov Inspector, New Zealand*, "Sexual Insanity in Inebriety," by Dr T D Crothers, Hartford, *Conn*

WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY —At the last meeting of this Society the following officers were elected for the ensuing year President—Samuel C Busey, M D,, Vice Presidents—D W Prentiss, M D and W W Johnston, M D , Treasurer—Geo Byrd Harrison, M D , Recording Secretary—Samuel S Adams, M D , Corresponding Secretary—C Wythe Cook, M D

VACCINATION FROM THE BUFFALO —The experiment has been tried in the Lahore district, India, during last year, of vaccinating from a young buffalo, instead of from a cow, and the results are said to have been "in every way satisfactory"

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U S ARMY, FROM OCTOBER 22, 1887, TO OCTOBER 28 1887

Major Chas R Greenleaf, Surgeon, will proceed from this city to the places hereinafter named, in the order in which they are named, for the purpose of investigating the methods of examining recruits at the depots and rendezvous located thereat, and of instructing recruiting officers in matters pertaining to such examinations Baltimore, Md , Philadelphia, Pa , Camden, N J , New York City and Davids Island, N Y , Boston, Mass , Portland, Me , Albany and Buffalo, N Y , Cleveland, O , Detroit, Mich , Chicago, Ill , Milwaukee, Wis , St Paul, Minn , Jefferson Bks and St Louis, Mo , Cincinnati and Columbus, O , and Pittsburg, Pa S O 248, A G O , October 25, 1887

Major P J A Cleary, Surgeon, ordered to proceed from Ft Huachuca to Ft McDowell and report to the commanding officer for duty as Post Surgeon S O 111, Dept Ariz, October 10, 1887

Capt Chas Richard, Asst Surgeon, granted leave of absence for one month, to take effect when his services can be spared by his post commander S O 247, A G O , October 22 1887

Capt H G Burton, Asst Surgeon, ordered from Plattsburg Bks , N Y , to Watervliet Arsenal, N, Y

Capt J C Merrill, Asst Surgeon, ordered from Watervliet Arsenal, N Y , to Frankford Arsenal, Pa S O 249, A G O , October 26, 1887

First Lieut Nathan S Jarvis, Asst Surgeon, ordered for field duty in Dept of the Platte S O 246, A G O , October 21, 1887

First Lieut Nathan S Jarvis, Asst Surgeon, ordered from Dept Platte to Dept Mo , for duty in the field. S O 249, A G O , October 26, 1887

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY, DURING THE WEEK ENDING OCTOBER 29, 1887

Medical Inspector N L Bates, ordered to hold himself in readiness for orders to the "Trenton"

Asst Surgeon F A Hesler, ordered to examination for promotion

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDING OCTOBER 29, 1887

P A Surgeon Bailhache, to proceed to Buffalo, N, Y , Erie, Pa , Ashtabula, Cleveland, Sandusky and Toledo, O , as inspector October 4, 1887

Surgeon C S D Bessenden, detailed as chairman of Board for the physical examination of cadets, Revenue Marine Service. October 15, 1887 To proceed to Cape Charles Quarantine Station as inspector October 26, 1887

Surgeon H W Sawtelle, detailed as chairman of Board for the physical examination of officers, Revenue Marine Service October 27, 1887

P A Surgeon Fairfax Irwin, to inspect unserviceable property at Boston, Mass , and Portland, Me , to proceed to Vineyard Haven and New Bedford, Mass , as inspector October 8, 1887

P A Surgeon F W Mead, detailed as recorder of Board for the physical examination of cadets, Revenue Marine Service October 15, 1887

P A Surgeon J H White, leave of absence extended four days October 21, 1887

Asst Surgeon P M Carrington detailed as recorder of Board for the physical examination of officers, Revenue Marine Service October 27, 1887

Asst Surgeon J B Fattic, granted leave of absence for seven days October 28, 1887

Asst Surgeon W J Pettus, when relieved at *Savannah*, Ga , to proceed to Galveston, Tex , and assume charge of the Service October 17, 1887 Granted leave of absence for thirty days October 21, 1887

Asst Surgeon J J Kinyoun, granted leave of absence for fifteen days October 19, 1887

TUBAL PREGNANCY, WITH SPECIMEN OF CASE.

Read in the Section on Obstetrics and Diseases of Women, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY C R REED, M D,

OF MIDDLEPORT, OHIO

The recent advances in abdominal surgery have given the subject of tubal gestation a new interest to the profession Before this advance in the treatment of extra uterine pregnancy, a diagnosis of ectopic gestation was followed by a prognosis equivalent to a death warrant to the unfortunate woman who was the subject of a misplaced embryo Under the title "Tubal Pregnancy," (and Mr Lawson Tait says "all cases are tubal in their origin") we include tubo ovarian, tubal, tubo uterine or interstitial, and abdominal, as practically these distinctions are of little importance We will not stop here to discuss the causes of ectopic gestation, as it is well known that if the ovum in its passage from the ovary to the uterus comes in contact with healthy spermatozoa, it is there impregnated, and fixes its habitation and commences its growth If fecundated while in the ovary or after it reaches the uterine cavity, it has room to grow to a mature fœtus, but if it meets the fertilizing element while in its narrow road, and loiters, it fixes its abode there, and while it has the power to appropriate the material or food necessary for its life and growth from the tissues surrounding it, it has not the faculties of reason and judgment to provide for the future by enlarging its home, as its growing needs require, and it violently assails and destroys its hostess

The proportion of extra to intra uterine pregnancies is given by Bandl as but one in 12,000, while Alexander Simpson states that many cases of hæmatocele associated with one or two months amenorrhœa are really extra uterine fœtations Many cases of sudden death in women from two to six months pregnant, are attributed to cardiac diseases, in which an autopsy would reveal Fallopian rupture from tubal gestation Mr Tait[1] states that he has known of twenty post mortem examinations of women who died from ruptured tubes Two have recently occurred in this vicinity, and I am of opinion that the anomaly is more frequent than heretofore believed

[1]Diseases of the Ovaries and Oviducts

Without an ante- or post mortem abdominal incision there is no way of demonstrating the existence of tubal pregnancy, the certain *proof* is wanting, in most cases there are but the usual symptoms of normal gestation until pain, shock and prostration occur, or what Barnes calls "abdominal shock and collapse" The gravity of the symptoms will depend on the extent of the rupture and amount of the hæmorrhage, if the latter is great, there is coldness of the surface, extinction of the radial pulse, pallor of the surface, whiteness of lips, tongue and conjunctiva, great muscular prostration while the mental faculties are preserved If the woman rallies from the shock, or death does not occur in the cold stage, then follow general peritonitis, with tympanites, and abdominal tenderness on pressure, dorsal decubitis, thoracic respiration, nausea and vomiting, high temperature, rapid and feeble pulse, septicæmia and death If the peritoneum is not ruptured, and the cyst passes into the folds of the broad ligament, hæmorrhage may be arrested, and but slight, the symptoms subside and the patient apparently recovers, but unless the embryo dies, it will continue to grow and a new danger awaits the doomed woman In the tubo ovarian form the pregnancy may continue to term, the fœtus dying is converted into an adipocire or a lithopœdion and may be retained an indefinite period, in one instance fifty six years Inflammation and suppuration may occur around the fœtal cyst, and it may be discharged through the walls of the abdomen, the vagina, the bladder or bowel The stage of gestation at which rupture takes place may vary from two weeks to several months, depending on the location of the cyst Rokitansky gives an instance of rupture in two weeks, and the average in tubal and tubo-uterine is probably two months

There are no pathognomonic symptoms, and the diagnosis is usually obscure Many of the prominent symptoms have been given in the history of the anomaly, and need not be repeated here If called to see a woman during the child bearing period, who has been suddenly attacked with pain in inguinal region or lower part of abdomen, attended with the usual symptoms of severe hæmorrhage, as shock, cold surface, clammy perspiration, absent radial pulse, pallor of lips, tongue and conjunctiva, and absence of external hæmorrhage with mental faculties intact, and on inquiry learn that she has missed one or more menstrual periods, that her breasts have been enlarged, and irregular enlargement of abdo-

men, with the ordinary attending nausea and vomiting, and without other means to account for her sudden illness, it may be presumed that she had extra-uterine pregnancy, that the tube was ruptured and severe hæmorrhage had taken place, and the subsequent history will confirm the diagnosis The presumption of ectopic gestation will be still stronger if the woman has been sterile for a number of years, for as stated by Tait, in his work previously referred to, "It is somewhat remarkable, and I think it is in favor of the views of the pathology of tubal pregnancy which I have advanced, that the majority of the instances of this abnormality occur in women who have not borne children previously, or in those who have had no children for many years This point in the history of the patient is therefore always noteworthy"

The prognosis, when gestation is attended by the above symptoms, is always grave Rupture of the fœtal cyst, with fatal hæmorrhage, in all cases of tubal pregnancy, may be expected at any period after six weeks or even one month In 500 cases collected by Parry rupture occurred in 174, or in 34 8 per cent Maygrier gives a table of fifty six cases of rupture followed by death, in only nine was the fatal result immediate, the deaths occurring from several hours to several days The prognosis is much more favorable under the improved methods of modern abdominal surgery With the expectant treatment as taught by Barnes and others up to within the past decade, the mortality was fearful, but now by prompt surgical interference, we may expect to save a large proportion The timid physician should not undertake the treatment of these cases, but call to his aid the bold, intelligent surgeon, in medicine alone there is no hope for the doomed woman, but in modern abdominal surgery she has a chance for her life

Treatment—The treatment of extra uterine gestation is curative, by the use of such means as will arrest the growth of the embryo or fœtus by destroying its life, as puncturing the sac and evacuating the liquor amnii, by injecting the sac with solutions of morphia, atropia, iodine, strychnia, etc , by passing a current of electricity through the embryo, all of these except the latter, we believe, have been abandoned, and of electricity Parvin says "Though the life of the fœtus be destroyed by electricity, the latter remaining in the abdomen of the mother may still be a source of disability, or even danger" The removal of the fœtus by elytrotomy or through the vagina has had its advocates, but is now abandoned for laparotomy or abdominal incision Thomas advises elytrotomy if the fourth month of gestation be passed and the tumor low down in the pelvis Maygrier takes the position that elytrotomy should not be done if the fœtus is living, but that laparotomy is preferable "In either operation the placenta should not be removed" Barnes[2] says "Lesouf has rightly said that every woman who has become the subject of an extra uterine gestation is doomed to more or less speedy death" This is eminently true of tubal gestation The question has often been discussed whether it is not advisable to perform gastrotomy with a view to removing the embryo and effused blood, and checking further bleeding by tying the Fallopian tube on the proximal side of the sac, and cutting away the sac I can hardly imagine that this idea will ever be successfully carried out in these cases of early tubal rupture In the first place, the greater number of subjects die within a few hours from the primary shock of the injury and hæmorrhage "Removal of the blood by gastrotomy must add to this shock, and cannot restore the lost blood I fear the actual state of science has no resource beyond the old one of rallying the patient from collapse by cautious administration of stimulants, of procuring rest by opium, and by controlling inflammation, if the patient survives until this conservative process sets in"

Later authorities in rupture of the cyst advocate immediate abdominal incision Parvin[3] says "The general practice is to endeavor, by external means, to arrest the hæmorrhage and sustain the patient" But in view of the recent successes of Mr Tait, who in less than three years has performed laparotomy in twenty one cases of tubal pregnancy immediately after rupture occurred, saving twenty women, it may be accepted that in all such cases, especially if grave hæmorrhage occur, the abdomen should be opened, the cyst, if possible, and its contents, with the clots, removed, the bleeding pedicle ligated, and the peritoneal cavity cleansed Mr Tait's success vindicates the position ably maintained by Stephen Rogers,[4] in 1867 This success, too, presents a striking contrast with the mortality of that expectant treatment Thomas states that in five cases of rupture of the sac, no operation being done, death occurred in four

Mr Lawson Tait[5] says "There are but two forms of misplaced conception In one the oviduct bursts, the peritoneum remaining uninjured, after which the ovum escapes into the broad ligament, between the folds of which its development continues In the other variety the peritoneum is lacerated as well as the walls of the tube, and the ovum finds its way into the cavity of the abdomen, and that tubal pregnancy may become intra peritoneal or extra peritoneal, just as the tube happens to burst The intra peritoneal termination is the more common, and the more fatal, while the extra-peritoneal development of the ovum is much rarer, less fatal, and far more amenable to treatment The class of cases which we see at the time of tubal rupture are generally included under the head of intra peritoneal hæmatocele I have very little doubt, however, that many of these cases would be saved by prompt action I have twice been on the point of performing abdominal section on account of suspected rupture of a Fallopian tube, and have been prevented by scruples as to the correctness of the diagnosis In both cases post-mortem abdominal section showed that the suspicion was correct, and I believe both

2 "Diseases of Women," 1873

3 "Science and Art of Obstetrics," page 314

4 "Trans American Medical Association," vol xviii

5 "Diseases of the Ovaries," 4th edition, written four years before the above quotation from Parvin

of these patients might have been saved A hesitation in opening the abdominal cavity was natural enough when we were overburdened with the superstition that it was a very serious step, but now that we know it can be done with perfect safety, I would not hesitate to explore in a case where I suspected a Fallopian rupture If my suspicions were verified I would apply a ligature to the rupture after I had completely emptied the sac, or I would completely remove the broad ligament, or perhaps stitch it to the abdominal wound and drain it, as I have done in pelvic abscess, etc In this way I think some of these terrible cases might be saved"

Mr Tait's recent successes, as quoted above from Parvin, verify his opinions as he predicted time and experience would The above quotations are inserted here, as they so well exemplify the following case

Mrs M, aged 37, mother of two children, youngest 14 years, of fine physique and health, was attacked on the afternoon of March 9, 1887, with pain in region of left ovary, with nausea and faintness, sufficient to confine her to bed until her usual bed time An effort to rise from bed would increase the pain and nausea As she had had similar slight attacks of pain the past ten days she thought little of it, and attributed the pain to ovarian neuralgia, to which she had been subject, and her husband being from home, did not send for a physician She had occasional pain during the night, but slept fairly well

On the following day, at 9 A M, I was called in haste to see her, as she was thought to be dying I found her pulseless at the wrist, her face, lips, tongue and conjunctiva apparently bloodless, surface cold, and about the only indication of life noticed was when I asked what was the matter She feebly responded she had a severe attack of neuralgia of left ovary, coming on when she arose from bed and was dressing She was a woman of much intelligence, with a good knowledge of anatomy and physiology On getting the above history of her case I said "Mrs M, you are having hæmorrhage" She answered, "No, I have had none" I asked if she had missed a menstrual period, she said, "One, and am near the next one"

Diagnosis—Tubal pregnancy with rupture of left tube and hæmorrhage into, probably, the peritoneal cavity She was given a full hypodermatic injection of atropia and morphia, she and her husband were told of the probable nature of her illness, and he was informed of a fatal prognosis and the necessity of immediate abdominal section, and consultants were sent for

At 1 P M she was again seen, in consultation with two physicians She had rallied slightly under the influence of the atropia, the morphia had relieved the pain, and there were indications of approaching reaction and a probable cessation of the hæmorrhage All of the counsel not agreeing in the diagnosis, an expectant course of treatment was adopted Stimulants and anodynes were given in small doses, large injections of hot water into the bowel by fountain syringe, which were retained and absorbed During the night of the 10th atropia, alcohol, and external heat were necessary to sustain animal temperature, and she barely lived through the night During the night there was slight hæmorrhage from the vagina, which did not recur An examination *per vaginam* was negative in results, *per rectum* indicated a large hæmatocele, or enlarged uterus, the latter proved correct

On the morning of the 11th condition slightly improved Radial pulse still absent, bloodless appearance, cold surface, mental faculties intact Same counsel Diagnosis large hæmatocele Treatment stimulants, anodynes, external heat, iced milk Prognosis more favorable

March 12, 8 A M Condition apparently improved, radial pulse now perceptible, 128, reaction, upper portion of abdomen resonant on percussion, lower dull or flat During the day abdomen became tympanitic and tender, peritonitis well marked with nausea and vomiting Treatment morphia hypodermatically, ice internally, calomel in small doses, and bismuth in large, to control vomiting, turpentine stupes over abdomen

13th Pulse 120, moderate force, paralysis of bladder and bowels, tympanites increasing, abdominal tenderness, nausea and vomiting, treatment continued, during the day vomiting ceased, iced milk and buttermilk were retained, calomel and bismuth discontinued

14th, 7 A M Pulse 124, less force, tympanites and tenderness continue, respiration thoracic, enemas of oil and turpentine moved the bowels freely, contents healthy, strength failing, mental faculties preserved

9 P M Mind wandering, strength failing, restless, breathing thoracic and shallow

15th, 5 A M Radial pulse absent, unconscious, died 8 A M, five days from the severe attack of pain and collapse

Autopsy, 16th, 8 A M, 24 hours after death On opening the abdomen in the median line from one-half to a gallon of fluid and clotted blood was found in lower abdominal and pelvic cavities The intestines were healthy, with no adhesions, general peritonitis, no decomposition of contents of peritoneal cavity After removing the blood search was made for the source of the hæmorrhage, on lifting up the left uterine appendages a rent was found in the Fallopian tube one inch from the uterus, a cyst nidus, the size of a common walnut (I present the specimen for examination) The uterus was large and erect, the right appendages healthy, these, with the uterus for reasons not necessary to state here, were not removed

Mrs M died, not directly from the loss of blood, but from its retention in the peritoneal cavity, exciting fatal peritonitis The details of this case are given, as I think it teaches a lesson A similar case, with specimen, was presented to the Philadelphia Pathological Society, Nov 12, 1885, by Dr Formad, and published in THE JOURNAL, Vol v, No 22, page 609 From the history of the above case, and the teachings of modern abdominal surgery, was the patient treated as the symptoms indicated? and did she have a fair chance for recovery? We answer, "No" We believe stimulants and an anæsthetic

should have been given, the abdomen promptly opened, the blood removed, the left appendages removed, the cavity cleansed, a drainage tube inserted, the incision closed, and Mrs M would have had at least two chances in three for recovery But other counsel prevailed, the expectant treatment was adopted, the old teachings of Barnes on tubal gestation, and Thomas on hæmatocele, were followed, and Mrs M 's life was a sacrifice to the ignorance and timidity of her physicians It might be said that in her collapsed condition operation would have been fatal Hot water should have been injected into the bowel, applied to the abdomen and extremities, the abdomen opened and the cavity irrigated with hot water, and she would have rallied from the shock On the third day, at the beginning of the peritonitis, there was sufficient reaction, and then, if not before, the operation should have been done

THE MEDICAL JURISPRUDENCE OF MENTAL AND NERVOUS DISEASES

Read in the Section on Medical Jurisprudence, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887,

BY S V CLEVENGER, M D,
OF CHICAGO, ILL.

Insanity may be regarded from three prominent standpoints the philosophical, the medical, and the legal How soon there shall be consonance of views depends upon when there shall be general recognition of what is known about mental diseases

Were the modern philosophical conclusions to prevail there would be no distinction between crime and insanity, society would simply adopt measures to protect itself against both as equally dependent upon faulty organization or function and more attention would be paid to circumventing the higher grade of criminals who seldom figure as such the demagogue, the social hypocrite, and the unscrupulous millionaire gambler It will be long before the populace comprehends that unjust judges, a Senate crowded with Neros and a feeble array of intelligence in the lower house can work more disaster than Bedlams and jails let loose, but the trend of enlightenment is toward mercy to the weak and protection against oppressors Dr Wm D Robinson, physician to the Eastern State Penitentiary of Pennsylvania, (in a paper read before the Philadelphia Neurological Society, March 28, 1887) says that the major part of state prison offenses were the acts of men born members of the crime class of people "They are one of the morbid excrescences from Society, and in progeny reproduce their peculiar kind As the cancer cell lodged in a neighboring gland develops a growth identical in make up with its paternal source so the offspring of the crime class belie not their origin

"These people very seldom reform, but in death end lives passed in crime and infamy They have absolutely as little control over their natural inclinations to wrong doing as the confirmed periodical drunkard has over desisting from his spree

"They really see very little moral wrong in their crimes—the crime with them being detection They truly believe that the man who assists in their detection and aids in their being brought under the law is much worse than themselves

"Crime is unquestionably a monomaniacal infatuation with them Statistics, attested facts and direct attainable evidence clearly warrants this assertion It is not an unusual case to have them acknowledge that they prefer the excitement of getting one dollar unlawfully to earning ten honestly"

Dr Robinson goes on to show that neurotic diseases, syphilis and defects of the cranial contents exist among them You are familiar with the disputations connected with the matter of responsibility in mental disease, and I will not trouble you with even a résumé thereof, but will ask your consideration of the philosophical view that criminality is madness

It is not so long ago in the World's history, that sickness of all kinds was regarded as a diabolical possession and among some primitive people attempts were made by harsh treatment of the patient to scourge away the evil When enough advance in reason had been made the sick were no longer held responsible for bodily ailments, but insanity was not regarded as depending upon any of the diseases to which mankind was subject, in fact it was not considered as a symptom of bodily disease at all

Finally, this concession was made, and mental disorders are in many countries classed as sickness for which the sufferer is not held to account, though in Illinois a jury still determines the extent to which a person is guilty of insanity, or, if we admit that the law recognizes insanity as a disease then a lay jury merely makes a diagnosis

Magnan and other pathologists, Crother and other clinicians, have demonstrated that many forms of inebriety depend upon defective organization Criminality and drunkenness being the product of structural faultiness it is as sensible to "punish" the sick as the malefactor

In sickness, insanity and criminality *discipline* is absolutely necessary, the delirium typhoid patient is prevented from leaving his bed and the rheumatic from eating unwholesome food In the better class of asylums the insane are promoted to better wards and more privileges as an inducement to cultivate self restraint, and this identical principle is operative to day in the Folsom (California) State prison where a graded system of fare is adopted for convicts according to their behavior

That Society is as yet unwilling to identify crime with insanity, on the grounds of inexpediency, does not disprove the identity and is paralleled by the inability of our ancestors to accord irresponsibility in mental ailments

Objections without number can readily be raised against a recognition of crime as insanity, one of the logical consequences of which would be the abolition of the penitentiary as a reformatory institution In considering this aspect of the question I would deny that reformation of criminality was accomplished by such imprisonment, and claim that the convict

who had served his term had merely graduated as a criminal, with of course here and there exceptions, which are such *in spite* of the system, the tendency of which is to confirm and to harden the convict The protection of the community, for the time being, that the incarceration affords, is obtainable through any method of sequestration and is no argument in favor of the brutalizing punishments resorted to

Legal gentlemen may laugh at this Utopian fancy, but let me tell them that penologists and alienists (who are not politicians) affirm that a large percentage of convicts are demonstrably insane from the standpoint of the layman, else why should there be a "crank department" in every such prison? I have known congenitally insane wretches to be forwarded to asylums after having been several years in prison with the statement that the lunatic had become so from the effects of imprisonment Paretic dements, who in the beginning of their mental breakdown often commit larcenies or outrages against decency are condemned as criminals and soon die in a convulsion or after a maniacal outbreak I have heard the question "What difference does it make, since death is inevitable, whether the patient die in the penitentiary or asylum?" The same might be urged in all cases in favor of an abolition of asylums and a return to the whipping, ducking and starvation methods of treating lunatics in recent centuries Besides, *ad hominem*, would it make no difference to your family that the truth had been recognized and you had been permitted to die as insane instead of as a convicted thief? The "insanity dodge" does not seem to have availed among poverty stricken culprits when we can recall so many grossly insane patients converted into convicts A pauper suffering from katatonia stabbed his wife in the most insanely brutal manner, exhibited all the peculiarities of that disease while in jail, but the political alienists and the jury forwarded him to the penitentiary where he was placed in the "crank department" A sixteen year old girl with hysterical insanity who attempted to poison her parents was also pronounced sane and sent to the same place, a paranoiac with *petit mal* who had shot two women for absurd reasons was given six years in the penitentiary The illegality of this sentence appears in the nature of the offence if committed by a sane person justifying, under present laws, a life sentence, but the suspicion that he was not "well balanced" caused the term to be shortened A life imprisonment in an insane asylum would have been more rational

Where insanity is suspected in a criminal the European method of preceding trials by an expert commision examination saves a great expense to the State and avoids the farcicalities so common in our American courts in similar cases, but as our peculiar institutions would, in nine cases out of ten, foist ignorant politicians upon us as members of such a commission, scientific alienists are not inclined to enthusiastically favor a change from the present faulty methods of lunatic inquiry

Many generations may come and go before the world can adjust itself to identify crime with insanity, but that eventually such a view will prevail appears to me to be inevitable as the outcome of progressive thought When that time comes there will be no penitentiary, for the asylum will quarantine against all who cannot conform sufficiently to social requirements, there will, furthermore, be no practical politician, as we understand him to day, for recognizing him as a member of the crime class his public treasury burglaries will be thwarted and the reason for his existence will cease

Alienists are too busily engaged in trying to convince the lawyer and the public that there should be no distinction between medical and legal insanity to undertake greater tasks, and it is this constant endeavor of higher knowledge to adapt itself to the conceptions of the period that causes such a thing as medical jurisprudence to exist It was formerly treason against God, king and common sense to deny witchcraft, all that could be done in defense was to prove the unfortunate not to be a witch I am not so shallow as not to foresee that many considerations would arise under such an adjustment that would require a great revision of our statutes, but I believe the Code would be greatly shortened and that criminal lawyers would be few in number, the main ground for contention would be the fact of crime commission

Polemics over accidental or designed acts would be abbreviated when the only object of the law would be to prevent a recurrence, and while Nature's failure to distinguish between a hand thrust deliberately or accidentally into the fire might not altogether be copied it could be thought of in disposing of the man who jokingly points an unloaded gun at another, for that species of imbecility is as deserving of regard as any other

So much for the future, but as an evidence that enlightened views are beginning to prevail we may note that the Wisconsin Senate passed a bill to send convicted drunkards to insane asylums, in spite of the teachings of ecclesiasts that drunkenness is a crime and not a disease

As however, in the present, responsibility is not to be discussed in court rooms from the philosophical side, it at least should be granted that the alienist is best able to consider the facts of insanity even from the legal and lay outlooks At once, then, it should be known that insanity cannot be dealt with as one and indivisible any more than sickness in general There are many kinds of insanity and a knowledge of their phenomena is requisite to an intelligent judgment For example, take one of the circular or recurrent forms such as katatonia, where the patient may be melancholic, stupid, maniacal, and then apparently rational, alternately Judge, jury and lawyers *cannot* pass upon such a case properly without a knowledge of these phases and as to whether the lunatic is or is not a katatoniac.

One with a head injury often becomes very intolerant of alcohol and upon occasion may commit some grave offense These and multitudes of as well established facts should be duly held up to view

There is such a malady as transitory frenzy, which may last hours or a less time and during which suicide

or murder may be accomplished I reported one such case in which a poorly balanced female head, under large doses of some abortifacient, attempted to throw herself from a window and cut her arm arteries with scissors Had the onslaught been made upon some other person she would have had great difficulty in proving her temporary insanity for it was of but brief duration

Witness poor John McCullough, the actor, wandering about with his delusions of grandeur and nearly every other evidence of paretic dementia fully recognized as such by able alienists who were unwilling to advertise their judgment and suffer the abuse of medical ignorami, even though time would have sustained the verdict

The German alienists more particularly have advanced psychiatry to a footing with many of the more exact provinces of medicine This is no less a truth because the fact is not generally known and that practitioners are often found who, like Fordyce Barker, are capable of appearing as experts in toxicology, gynæcology, surgery, ophthalmology and psychiatry

The olden dictum that the depths of one's attainments are inversely as their breadth, while needing some qualification, applies in such cases, for medicine has differentiated and developed beyond the possibility of any single person attaining proficiency in all The shoemaker may as well attempt to discuss the relative merits of Jurgensen and Waterbury watches as for the medical specialist in one line to pass judgment upon another

If some legislative provision were made for insane criminals and the criminal insane as was suggested by Dr Dewey, of the Kankakee Asylum, judges and juries might see their way clear to a more rational disposition of such cases as popular condemnation impels them to pronounce "sane but illy balanced"—"not insane but a crank'—"responsible for his act but of a low grade intelligence"

Especially should medical men insist not only that physicians should be selected as superintendents of asylums but, if it is not asking too much, that such physicians should know something of insanity Recently, in Chicago, lawyers were allowed to nominate candidates for judgeships from among themselves Why would it not be as well to permit physicians to select the heads of medical institutions, instead of relegating this power to saloon keepers, gamblers and prize fighters, some of whom, at least, are indicted thieves and more are justifiably suspected to be

At first glance it might seem advisable to compel asylum officials to keep full records of all cases admitted, and to have some more careful method for the receipt and discharge of lunatics, but as brains and scientific ability cannot be legislated into the heads of medical politicians the records kept by such a one would be valueless and the liberation of dangerous paretics can only be prevented by the asylum physician knowing a little about insanity, the recommendation that respectable alienists should be appointed to superintend asylums would cover the points better than the legislation named The Illinois State Legislature has been appealed to with regard to enacting some suitable punishment for attendants who illy use, wound, or occasionally murder the insane, but time is taken up by fisticuffs among the honorable members and calcimining self investigations covering alleged steals

Then as to the status of the expert in court He is usually selected by one side instead of by the judge and theoretically is presumed to be unbiased He is placed in a false position, for being the recipient of a fee from one side his allegiance would seem to be due to that side and were his testimony harmful thereto he would, with some show of justice, be considered as having betrayed his trust

There seems to be but one honest position for him to assume that of a partisan who may coach the lawyer who engages him If he can conscientiously, in addition to this, go upon the stand as an expert his convictions should be freely expressed and the lawyer should take his chances with such testimony just as with that of any other witness whom he calls

Ray's suggestions are good

1 That the expert should be asked if he gave his entire time to the study and practice of one branch of medicine, and if that branch was psychiatry

2 That the expert opinion should be rendered in writing which would cause legal trickery to be harmless

These suggestions apply equally well to neurological cases which are mainly actions against corporations for spinal injuries wherein Ericson figures largely for the plaintiff against Page for the defendant In a disorder that presents such a preponderance of subjective symptoms as spinal concussion, and in all other cases where simulation might be alleged as in paralysis, contractures, etc, the value of faradic and galvanic tests of muscles and nerves should be more fully appreciated, especially since with the milliampèremeter and Erb's electrical charts we have the means of graphically presenting the conditions ascertained in such a manner that the jury may readily comprehend

---

THE USE OF THE CURETTE AND INTRA-UTERINE DOUCHE AFTER LABOR AT TERM

Read before the Chicago Medical Society, September 19, 1887

BY J SUYDAM KNOX, M D,
OF CHICAGO, ILL

I think it will pass unquestioned that the sole object of washing out the uterine cavity, or of using the curette within it, post partum, is for antiseptic purposes Septicæmia or putrid absorption is possible during the puerperium of every woman If, therefore, these operations are perfectly harmless, they should be freely performed as a prophylactic measure, and should be heartily endorsed by obstetricians

If, again, the uterine cavity be the common origin of the septic and inflammatory accidents of the lying in, again should the curette and the intra uterine douche be used at the first signals of such abnormal disturbance

If, however, these operations be dangerous, requiring extreme care and precision, if, further, most of the inflammatory and many of the septic affections of the puerperium have not their origin in the womb, then the use of the intra uterine douche and the curette should be discountenanced, except in the hands of the skilful, and in the presence of positive indications

This brings us at once face to face with two questions, viz

1 To what extent, after labor, are douching and curetting the uterine cavity harmless?

2 What proportion of puerperal inflammations and septic fevers have their origin in the uterine cavity?

Let us consider these questions in order

1 To what extent, after labor at term, are douching and curetting the uterine cavity harmless? At first sight it would seem almost useless to quote authorities in answer to this question Scarce a writer on obstetrics, in describing these operations, but writes with precision and minuteness of detail emphasizing caution and precaution I have time to quote from but one or two

Lusk[1] says "The operation of cleansing the uterus should be conducted with the most scrupulous care Intra uterine injections should be resorted to with extreme circumspection Among the accidents which have been referred to the use of injections, are convulsions, shock, and carbolic acid or corrosive sublimate poisoning, but the chief danger lies in the possibility of conveying the infectious material from the vagina to the previously normal uterus" Then quoting Carl Braun, of Vienna, he says[2] "Braun von Fernwald, with his vast opportunities for judging obstetrical questions, writes in reference to this 'We must protest against injections made by physicians into the uterine cavity—such meddlesomeness is more likely to do harm than good'" "This," says Lusk, "corresponds with my own experience"

Charpentier[3] writes "A certain number of accoucheurs in France, and eminent ones, are afraid of intra uterine injections, and look upon them as more harmful than useful"

Although an earnest advocate for intra uterine douches where "strictly indicated," Charpentier emphasizes this[4] "Let it be understood, however, that intra uterine douches are to be administered with care, and *always by the physician himself*"

Hofmeier[5] administered intra uterine douches after 260 cases of normal labor, 42 of these presented more or less serious symptoms In another series of 240 cases of normal labor no intra uterine douches were given, only 19 of these women presented any unusual symptoms Paul Bar,[6] speaking of the dangers of these douches, says "After the injection is given, we occasionally see some alarming symptoms develop, the woman becomes pale, she faints, soon she complains of severe pain in the hypogastric region, then she experiences the greatest anguish These symptoms may be temporary But sometimes they assume the greatest gravity, and death may supervene immediately or after a few hours"

The above quotations from writers of large obstetric experience, and practicing the operation under the most favorable circumstances, are sufficient to show that intra uterine douches are by no means harmless

I do not hesitate to acknowledge that many, possibly a majority of the obstetric teachers of to day are advocates of intra uterine douches, some of them, like Schultze, Schulein, and Grunewald advising them, as a prophylactic, after all labors This, however, does not affect the conclusion that they are *not* harmless

There is a vast difference between the conscientious care, exact methods, and skilled operations of Continental maternity obstetricians, and the practice of our average accoucheur If only one of the gentlemen before quoted has found such douches occasionally harmful, then are they dangerous, yes, at times murderous, in the hands of the careless many The most enthusiastic advocates of the intra uterine douche insist that it must be administered with the most scrupulous care The external disinfection of the patient, the thorough disinfection of the operator, the aseptic injector passing through a thoroughly aseptic vagina, the exact temperature and force of the injection, the entire exclusion of atmospheric air from the uterine cavity, the free drainage—in fact all the details of the operation, not one of them must be omitted Leave out the simplest of them and the whole method is vitiated The arch loses its strength by the removal of a single stone

How absurd even to expect this of the average practitioner, or average obstetric nurse How vicious, unless positively indicated, and antiseptically practiced, to deliberately accept the risk of infecting the uterine cavity

Since the use of the curette necessitates the subsequent use of the douche, the risks of the latter apply to it In addition are the necessary admission of air into the womb, the creation of further wounds, the provocation of hæmorrhage, the shock of operation and the possible perforation of the uterine wall

2 What proportion of puerperal inflammatory and septic fevers have their origin in the uterine cavity? Not what is the *cause*, but whence the *source* of these puerperal accidents?

The fact that a woman is parturient does not protect her against the inflammatory and zymotic diseases common to her sex or to mankind Her puerperal condition may gravely modify the normal course of an invading sickness and cloud the prognosis, but it does not influence the origin Parturition is no specific against malarial manifestations, nor contagious zymotic diseases, neither does it protect from acute inflammations of mucous and serous surfaces, nor traumatic inflammations of cellular tissue and gland organs Supply approximates causes, and they all arise equally before, during, or after gestation Such intercurrent maladies often retard

the convalescence of the lying in woman, and can proceed to a fatal termination without the slightest evidence of sepsis It is not necessary to quote authorities in defense of this There is no dissent from it

In this age, when nearly every puerpera having chill and rise of temperature is treated with the intra-uterine douche, according to Schultze's idea "that we must adopt some aggressive form of treatment, and treat each puerperal woman as if she already had puerperal fever," it seems to me necessary to protest against so pernicious a practice Such a procedure in purely inflammatory puerperal accidents is not only thoroughly unreasonable, and a confession of lack of skill in differential diagnosis, but it is dangerous There is the greatest risk of introducing septic and putrid material into a uterine cavity that is probably entirely aseptic

Equally well recognized by obstetricians is the fact that a majority of the inoculations of parturients arise anterior to the uterine cavity The practice in Continental maternity hospitals sufficiently proves this

In the Prague Maternity, under Prof Breisky,[7] labor is conducted antiseptically When evidences of sepsis appear, antiseptic vaginal irrigations are practiced They seldom have recourse to intra-uterine douches These are always made by the physicians

In Copenhagen Maternity,[8] under Prof Shufeldt, intra-uterine douches are only used when there is positive evidence of putrescence in the uterine cavity Otherwise vaginal antiseptic injections are administered The methods of Tarnier[9] and Charpentier, of Paris, and Spaeth and C Braun, of Vienna,[10] are practically the same Vaginal injections are the sole post partum antiseptic treatment, unless there are positive evidences of septic inoculation of the uterine cavity

Garrigues,[11] in the Maternity Hospital in New York, discards both vaginal and intra uterine douches, and believing that septic infection post partum originates at the orifice of the parturient canal, uses his occlusion bandage with remarkably good results

Lusk,[12] in the last edition of his work on obstetrics, in summing up this subject, says "Intra-uterine injections are not indicated by a simple rise of temperature A very large proportion of the febrile attacks which occur in childbed run an absolutely favorable course Unless the infection (and this is not the rule but the exception) proceeds from the uterine cavity, they are unnecessary "

If, then, the post-partum use of the intra-uterine douche and curette be not harmless in the hands of the most skilful, and is dangerous as used by the careless, and if, further, there are many inflammatory accidents of puerperæ that are not septic, and many septic accidents that do not arise within the womb, when shall we administer them? I would formulate the following rules

1 Where there is positive evidence that there is putridity or septic infection of the uterine cavity, the douche is imperatively demanded

2 Where the douche does not succeed in abolishing the fetor or septic symptoms, the curette should be cautiously and thoroughly used

3 Where the womb has been thoroughly irrigated and made aseptic, the douche should be discontinued

4 Where there is septic fever, with doubt as to its uterine origin, vaginal antiseptic douches should be first attempted. Only on their failure should intra uterine douches be resorted to

5 In purely localized inflammatory affections, with no evidence of sepsis, the intra-uterine douche is absolutely contraindicated

6 The intra-uterine douche should never be used simply to lower temperature

And as a corollary to the above should be added

7 It should be considered a criminal offense to administer an intra uterine douche without proper antiseptic precautions, or to intrust its administration to an unskilled assistant

Lest this last be considered too harsh and arbitrary, I would explain that it is a slow outgrowth from observation of the practice

There is a growing tendency, in this germ crazed age, to charge every deviation from a normal lying in to bacterial agency, which I believe to be wrong There is also a growing tendency, on account of the brilliant results obtained in maternity hospitals, to apply the methods of such hospitals to private practice I do not object to the methods, but I do strenuously object to this application The fact is, the influences affecting the two classes of parturients are radically different The best results obtained in maternities to day, under strict antiseptic precautions, do not exceed those of ordinary private practice without special antisepsis Besides, it is not possible to carry into private practice the routine of the hospital Whenever the influences *are* similar, the same methods should be rigidly enforced

Again, in the practice of these methods I earnestly and solemnly protest against the divorcement of the technique from the operation The intra uterine douche or the use of the curette is valuable, not so much because the injection is antiseptic, or the *débris* is removed, but because it is done antiseptically Unless so done it is worse than useless

This growing easy faith in the harmlessness of uterine irrigations administered carelessly, and often entrusted to unskilled and ignorant nurses, is to me appalling

I would close this brief paper with two quotations which fully express my views The first is from Egbert H Grandin, M D , of New York [13] "There is one point in regard to the intra-uterine douche on which sufficient stress cannot be laid, and this is that it is useless, and is not indicated, except where the source of infection lies in the cavity of the uterus Exudations around the uterus, whether of septic or traumatic origin, are not benefited, but may be, on

the contrary, intensified by manipulation of the uterus Fœtor, rise of temperature, chill, may depend on a lesion of the vagina or cervix, as well as on infection from the uterus We must first differentiate the source of the infection, as nearly as may be, and where in doubt, in the absence of evidence of cellulitis or of peritonitis, it is a good and a safe plan to give, with care, one thorough intra uterine douche "

The second is from the pen of Lusk [1] "It cannot be too strongly insisted upon that, in a rightly conducted confinement, infection does not begin in the uterine cavity, and that the need of such injections is a confession of faulty procedure "

OPERATIONS FOR MASTOID DISEASE

Read at the Thirty Seventh Annual Meeting of the Illinois State Medical Society

BY SETH S BISHOP, M D

CHICAGO SURGEON TO THE ILLINOIS CHARITABLE EYE AND EAR INFIRMARY, TO THE ILLINOIS MASONIC ORPHANS' HOME ETC

The purpose of this paper is to increase your confidence in operations on the mastoid process Some physicians, for whose attainments I hold the highest regard when matters of ordinary surgical experience are under consideration, have questioned the expedience of surgical interference in mastoid disease Principles that are admitted to be unimpeachable in general practice, have been disputed when applied to the treatment of mastoid abscess and necrosis No surgeon denies that free and early exit should be given to confined accumulations of pus, yet this correct surgical precept is not only neglected, but advised against by some of our excellent practitioners Being fortunate enough to have had a very gratifying experience with several cases in which operations were imperative and successful, I desire to impress you, as I have been impressed, with the necessity, safety and success of these operative procedures

A few words may be profitably devoted to the subject of

PREVENTION OF MASTOID PERIOSTITIS

and abscess I have often dissipated an incipient inflammation of the periosteum by means of counter-irritation with cantharidal collodion or essential oil of mustard, applied generously over and below the mastoid process I endeavor to produce as active irritation as possible without vesication, and for this purpose the mustard oil is superior, although its volatile quality renders it disagreeable to both patient and surgeon I have had numerous cases in which these remedies were not applied until after pain, redness, swelling and tenderness were marked, and yet these irritants used once or twice a day for a few days caused the inflammation to subside, and saved patients from the agonies of mastoid abscesses Leeches, poultices and rest, with antiphlogistic remedies, will frequently effect the same result But let us suppose that the opportunity for these measures is past, and that the formation of pus is inevitable, or that fluctuation is already present, what is the best course to pursue? What, but the same that we adopt in similar conditions in other parts of the body? A free

INCISION

with a strong knife should be made clean down to the bone, and from a half inch to an inch and a half long The cut should extend over the most prominent portion of the swelled mastoid tissue, directed from below upward, parallel to the attachment of the auricle Should no pus escape immediately it will likely do so in a few hours, and we shall have dispelled the exquisite pain by relieving the stretched nerves of their unnatural tension Free bleeding will probably occur from the divided posterior auricular artery, but this only depletes the over distended vessels—adds water to the fire, oil to the burn A grateful sense of relief comes soon, and we may confidently expect all the symptoms to be ameliorated If no caries be present the wound should be cleansed, and dressed with finely powdered boracic acid, absorbent cotton and antiseptic gauze bandage, with a drainage tube or tent in the lower end of the wound

So far we have dealt with a periostitis, or an abscess, in the course of which the disease has not invaded the bone Although such cases are the concomitants of suppurative otitis media they are quite amenable to the preventive and curative treatment outlined above, associated with treatment directed against the middle ear disease, so long as the integrity of the bone is not affected Let us now pass to the consideration of necrosis and the operations for

OPENING THE MASTOID CELLS,

After Wilde's incision has been made, as described above, the surface of the bone should be thoroughly explored with a firm probe to discover any caries or a sinus which might exist If there is no more serious condition than superficial caries, this should be dislodged with the chisel, gouge or curette, care being taken to preserve all the periosteum When dead bone is to be removed it becomes necessary to make a secondary incision, extending backward, at right angles to the middle of Wilde's incision in order to get sufficient space for the use of bone instruments When a sinus is found I make the two incisions meet directly in the sinus, dissect up the periosteum and over lying tissues, and have the flaps retracted and held out of the way by assistants If the opening is a small one it should be enlarged with a small drill sufficiently to afford free drainage and to remove all the diseased bone I have found the openings effected by nature in some cases too large and irregular to admit the use of either drill or trephine In such cases the chisel, gouge and curette are required Occasionally one may find spiculæ of bone loosened which he can remove with the ordinary dressing forceps, with a little careful manipulation to detach it from its irregular surroundings When there is quite a large area of bone denuded of its periosteum we may find, on pressing the finger upon it, that it gives, as though it were

[1] Loc cit

hung on one side by a stiff steel spring In such a case the line of demarkation between the healthy and diseased tissue should be sought, and the division be effected by the delicate chisel and mallet A trephine may be useful also for this purpose if one can find a firm place for its fixation shaft In using the chisel one should be sure that it is sharp and properly shaped, and that the blows of the mallet are light, otherwise more bone than we wish to remove may be taken It has happened to me in a case where the necrosis was very extensive that the whole lower portion of the process has given way under a dull chisel, carrying with it some healthy bone, and exposing the dura mater The chisel was not properly tempered and beveled, and the cutting surface chipped during the operation After all the superficial dead bone has been removed and the edges of the sinus rimmed out and made smooth by the conical drill, we may find the cellular tissue of the process diseased and filled with dark red, ugly looking granulations The curette, adapted in size to the circumference and contour of the opening in the bone, should then be employed with the utmost caution to avoid injury to the dura mater, the lateral sinus, or the middle ear Frequent stops should be made to examine the tissues we encroach upon and to determine when we reach sound parts Small sponges used frequently will free the wound of blood so that we can make satisfactory examinations of our progress, and if the bleeding is considerable it is advisable to have an assistant syringe the cavity at every step with a warm solution of mercuric bichloride, 1–10,000, so that we shall make it impossible to remove tissues that should be left intact In this way I have removed diseased bone until portions of the inner table were taken out, the dura mater exposed and the pulsations of the brain were visible, and yet have avoided harming the dura mater, as the subsequent progress of the case demonstrated

In using the trephine or drill the instrument should be directed upward, forward and inward, as a rule, but the location of the sinus, if one be present, or the place selected for opening the bone, must help to determine the direction of the instrument The pressure exerted on the drill or trephine should be very light, for fear that the outer layer may be unusually thin, and that the instrument may suddenly settle into the soft tissues beneath The thickness of the outer layer will average from an eighth to a quarter of an inch In children it is very thin, while in adults I have found it nearly a half inch thick

The operation ought not to be ended without syringing the wound, cleaning out all the debris and examining the cavity minutely by the aid of strong illumination made brilliant by the concave mirror if necessary It requires the closest scrutiny to prevent the overlooking of small particles of diseased and dead tissue Should we not be successful in removing all of this, the erosion may extend and require a subsequent operation But the necessity of a repeated operation does not perforce argue that all the necrosed bone was not taken at a previous operation I have several times removed diseased bone from a mastoid process which had been operated on before by a competent surgeon At each operation the most critical inspection, under brilliant artificial illumination, has satisfied all the surgeons present that no unhealthy tissue remained But this occurred in an extremely unpromising patient of a strumous diathesis, upon whom I operated to prevent meningitis and cerebral abscess Nearly the whole mastoid process crumbled away, and some time after the third operation I found the incus lying loose in the wound

It is remarkable how rapidly a suppurative inflammation of the middle ear may involve the mastoid cells in caries, and how extensive the necrosis may become after a few weeks' duration I have seen cases that were discharging pus from a sinus which had existed for three weeks only, and where the advent of the sinus was preceded by no more than four or six weeks of suppuration of the middle ear, if the statements of patients and friends were to be credited Upon enlarging the opening I have had to scrape away unhealthy granulations and dead cells with the curette, until the mastoid process was literally converted into an empty cup, before all the products of disease were removed

If my observations are correct, the rapidity of this destructive process is greater in children than in adults It follows, then, that it is better to operate early, when the case requires it, to prevent extensive necrosis, and the vigor of youth renders the prognosis the more favorable

It is a custom among some operators to leave the edges of the cut gaping, and to fill the cavity with lint, that it may heal from the bottom I have preferred syringing the parts with the bichloride solution, dusting them freely with iodoform, inserting a drainage tube at the bottom of the wound, sewing it up and dressing it with absorbent cotton and a bandage of antiseptic gauze With this treatment there is but little subsequent discharge The case is seen daily and dressed as often as cleanliness and antisepsis require

I have entered thus minutely into a description of this operation for the reason that it is rarely performed except by specialists, and although I have enjoyed the ample opportunities offered by the surgical clinics of New York, I never had the advantage of witnessing the operation until I first performed it Yet I must say that the results in the first case were not surpassed by those in any other The patient was a young man, 18 years old, with a discharging mastoid sinus accompanying a chronic suppuration of the middle ear The caries was extensive and the hearing much impaired I removed all the dead bone without sacrificing any of the periosteum, and followed a course of treatment adapted to the condition of the middle ear, with the result that in fifty six days the wound had completely filled in and healed with hard cicatricial tissue, and the tympanic disease was cured I met the patient on the street a short time since and he stated that he had experienced no further trouble, and that his hearing was as good as ever it was before the operation

For the sake of brevity I will give but a skeleton

sketch of one or two other cases An interesting one is a boy 6 years old, who had scarlet fever, followed in two weeks by an acute suppurative inflammation of both middle ears Two months later, when I first saw him, a mastoid abscess had developed, necessitating Wilde's incision Exploration with the probe revealed a sinus and softened, roughened bone I was unable to obtain his parents' consent to an operation until three months later, when I operated at the Chicago Medical College In the meantime I had succeeded in curing the suppurative process of the middle ears and had kept the sinus cleansed with solutions containing boracic acid, carbolic acid, mercuric bichloride, iodoform, the hydrogen peroxide, etc Anæmia and malnutrition demanded tonics and alteratives, whereupon he grew fat and plethoric At the operation it was found that a large part of the external layer of the process was denuded of periosteum, the bone was black and movable, and the cells were filled with very dark, unhealthy looking granulations and pus After removing all the diseased tissue the wound was dressed antiseptically, and in eighteen days had completely healed and the patient was well Some weeks later, while the boy was at play with his companions, he received a blow over the cicatrix, which was followed by an acute inflammation and suppuration A small spicula of healthy looking bone, which the blow might have detached, protruded from the wound and was picked out The wound then healed and opened several times, and when I last saw the patient there was a pin hole opening and an oozing of a drop of sero purulent discharge in the course of the twenty four hours This patient has made a complete recovery

The only other case in which the results were not completely curative and satisfactory, was the one already mentioned as a bad case of scrofula It was a woman in whom all the lymphatic glands were enlarged, she was emaciated, anæmic, without appetite or strength, and required the most invigorating and supportive treatment both before and after the operation I should not have felt justified in operating were it not for the fact that the patient would likely have died of exhaustion, pyæmia or cerebral abscess, if the extensive necrosed tissue were not removed and the suppuration stopped She had been operated on five months previously, but the wound had never closed or ceased to suppurate When she left the hospital the wound had not entirely closed, and there was a slight discharge, but no dead bone She was permitted to go to the country on condition that she should return for treatment three times a week until cured I never heard from her again

These two are the only cases in which the cure might not be said to have been complete before they passed from under my observation, and during the past year I have had seven patients under my care in which the operation was imperative Two of these cases were operated on by my colleague at the Illinois Charitable Eye and Ear Infirmary, Dr F C Schaefer

The arguments in favor of the operation may be summarized as follows Three fourths of the cases were completely cured The remainder were benefited None were worse for the operation Nature's method of opening abscesses and casting off dead bone is slow and uncertain The presence of confined pus threatens necrosis, and the presence of necrosis and pus threatens meningitis, cerebral abscess, pyæmia and death

THE CHOICE OF GENERAL ANÆSTHETICS IN SURGERY AND OBSTETRICS

Abstract of a Paper read before the Medical Society of Virginia, October 19, 1887

BY HUNTER McGUIRE, M D,
OF RICHMOND VA

Beginning with a denial of the common statement that the use of any anæsthetic lessens the success of operative surgery, Dr McGuire mentioned that chloroform is the popular anæsthetic used in France (except in Lyons), Germany (except in Vienna), and in Italy In Great Britain, mixtures of ether and chloroform are principally used In China, chloroform is chiefly used In the United States, ether is the popular agent throughout the Northern and Northwestern States, while chloroform is the generally adopted anæsthetic of the Southern and Southwestern States Thus it will be seen that throughout the civilized world, chloroform is much more generally used than ether Combining the obstetrical cases in which anæsthetics are used with the surgical, it may be safely estimated that chloroform is used twenty times as often as ether as the anæsthetic—the two agents to which he restricted his paper He predicted that when a full analysis of all the facts is finally made, in certain cases it will be determined that ether should be given, and chloroform in certain other cases—thus establishing the special value of both In general terms, in the feeble or anæmic, or in those prostrated by shock or loss of blood, he prefers ether, but when there is cardiac, renal or pulmonary trouble, chloroform is preferable Up to the present time between 400 and 500 deaths from chloroform have been reported, and about 100 deaths from ether, but he was unable to say what the ratio of deaths by either agent is to the total number of administrations Sphygmographic tracings during chloroform anæsthesia show depression of the circulation, this is only occasional, and then not so marked when ether is given Hence cardiac paralysis is more likely to follow the use of chloroform But experience proves that when chloroform is withdrawn, and consciousness returns, the patient is safe But this is not the case after ether is withdrawn Even acute nephritis or pneumonia occurs sometimes as the result of the use of ether In short, in diseases of the kidneys or lungs ether is more dangerous But both may kill—especially chloroform, by using a too concentrated vapor during the period of muscular excitement, by paralysis of the respiratory nervous centres

In selecting an anæsthetic, Dr McGuire is somewhat governed by the character of the assistant who is to administer it In inexperienced hands, ether is the safer To give chloroform requires one who

knows, and will attend to his business alone One accustomed to give ether is not usually the one to select to give chloroform To ask a patient to take long, deep or rapid inhalations of chloroform vapor is dangerous The greatest danger from this agent is in the early stage of its administration, when by a too concentrated vapor or its too rapid use, the heart centres may be surprised and overwhelmed When using chloroform, it is safer to let the patient's head be turned to one side, so as not to let the concentrated vapor—being four times heavier than air—exclude the atmospheric air Begin with a small quantity, allow a plenty of fresh air and gradually accustom the patient to the vapor Never give chloroform in a hurry

The giving of alcohol as a heart stimulant just before giving chloroform is open to serious objections In the first place, who knows what the stimulant dose is in individual cases? In the next place, alcohol increases the duration and stage of excitement, and makes nausea, etc, more likely to occur We all agree that those addicted to the free use of liquor are bad subjects for anæsthetics

The speaker mentioned a recent publication by an eminent New York surgeon, advocating the giving of a very small dose of chloroform in concentrated vapor, on the ground that if alarming symptoms set in, this amount could be speedily pumped out of the lungs by artificial respiration This is dangerous doctrine to teach In the only fatal case by chloroform coming under his observation the heart stopped *suddenly* The heart did not previously flutter, grow weak nor intermit, but abruptly ceased It was like the syncope of concussion of the brain, the contractile power of the heart was annihilated We may remove by artificial respiration in such a case all of the vapor, but we cannot in this way remove the impression made on the nerve centres which stopped that heart's action

Although frequently taught, we are apt to forget that we should never operate during partial anæsthesia Many deaths from chloroform are due to not heeding this advice that comes of experience Fatal syncope may come on from the consciousness that the painful operation is yet to follow, or if intellectual consciousness is just lost, there seems to be left, so to speak, a consciousness in the nerve centres of the heart and lungs, and the impression of pain on them is fatal Ether is safe when an operation is to be performed under partial unconsciousness In operations in which blood or other fluids may escape into the windpipe, chloroform is the safer Dr McGuire does not think he ever saw the irritability of the larynx or trachea entirely lost in chloroform anæsthesia, but he has seen it in ether anæsthesia Possibly the cold vapor of the other may in a measure account for this loss of reflex excitability in the throat

In organic heart diseases, he has never had occasion to regret the choice of chloroform, but ether is preferable in a nervously weak heart, as also in cases of weakness from fatty degeneration, or loss of blood, or great anæmia from other causes, etc In such cases any anæsthetic is hazardous, but ether is safer

Of all the elements of danger from chloroform, fear on the part of the patient, he believes to be the most important and the most frequent The heart becomes nervously weak If a calm, confident manner on the part of the administrator does not allay this fear, give hypodermically a quarter of a grain of morphia sulphate, with a one hundredth of a grain of atropia sulphate, and wait fifteen minutes or so for the physiological results before giving the anæsthetic Emotional excitement greatly increases the chances of paralysis of the nerve centres presiding over the circulation Morphia obtunds this sensibility and also acts as a cardiac stimulant, and atropia is probably a more powerful stimulant That emotional excitement is an important element of danger he believes all administrators will admit

Children take chloroform well and safely They are not afraid of being killed by it Nussbaum has seen 40,000 administrations of chloroform in military life without an accident Dr McGuire has seen, as Medical Director of Stonewall Jackson's Confederate Army Corps, 28,000 chloroform administrations without causing a death Neither the age, sex, health, etc, of the soldiers could account for this The wounded soldiers dread the hazard of chloroform very little It is also significant that chloroform has been given to hundreds of thousands of women in labor, with but one fatal case, so far as he has learned, and in this instance it is by no means certain that death was due to the anæsthetic Even when surgical operations have been required in obstetrical cases, no death has followed the use of chloroform The recumbent position does not explain all this exemption, nor do the pains of labor, for we have pain from the surgeon's knife, etc The element of success in all such cases, Dr McGuire believes, to be the want of dread of chloroform

Dr McGuire deplores the partisan debates which have occurred on this subject of the choice of anæsthetics In the last text book on surgery issued this year, is the following "In general there is no comparison between these agents, ether is so much safer than chloroform that the latter is fast disappearing in practice The estimated death-rate after ether is 1 in 20,000, in chloroform, 1 in 3000" Such statements are the outcome of prejudiced brains, and are absolutely unwarranted by any facts or figures known to the profession

COTTON GRAFTING

BY M PERL, M D,
OF HOUSTON, TEXAS

Absorbent cotton is far preferable to sponge for grafting purposes, as it is always ready and at hand, requiring no preparation for its use, while the preparation of the sponge is a tedious process, and it must be kept in air-tight vessels immersed in an antiseptic solution The following case will illustrate the *modus operandi*

Eliza Roy, female, 18 years old, was treated by me from October 18 to November 12, 1886, for cerebro spinal meningitis She made a good recovery, with the exception of an indolent ulcer three

by five inches and one half inch deep, the edges callous and turned under, resulting from a severe burn on the lower part of the right leg, caused by the application of a hot iron to her feet, one night, while in a semi comatose state, during the acme of the fever The burned place was not noticed until she complained of it some fifteen days later, when my attention was drawn to it

From that time on till April 15, I used all possible topical applications, gave tonics and prescribed a generous diet, with wine, but all to no purpose I then thought of sponge grafting, but, having none prepared, concluded to try absorbent cotton in its place The day previous I had applied a thick coating of cantharid collodion to the ulcer, which caused the surface and edges of the same to be slightly inflamed This seemed to me the best time to apply the graft A piece of absorbent cotton, the exact size and thickness of the ulcer, was saturated with a solution of corrosive sublimate 2 1000, the surplus liquid was expressed and the cotton smoothly adapted to the surface of the ulcer and held in its place by strips of adhesive plaster, over which a layer of borated cotton was spread This was covered with antiseptic gauze and the whole surface was then closed with strips of rubber plaster, making as tight a covering as possible

April 17 —The discharge being moderate, the bandage was not disturbed

April 19 —Plaster, gauze and borated cotton were removed, and adhering puss was removed by a spray of corrosive sublimate of above strength, the graft adhered firmly to the surface of the ulcer, leaving only a small space between the edges of the cotton and the ulcer, to which a solution of nitrate of silver, 1 30, was applied, and the bandage adjusted as before

April 21 —After removing the bandage the cotton graft had a pinkish color, was raised slightly, adhered firmly, and the space between the edges was much smaller The same dressing was applied

April 23 —The graft filled the whole space, adhered firmly, and was of a uniform pink color, the edges of the ulcer were flat and extended over a small portion of the graft, same dressing

From that day on the ulcer decreased in size at each dressing, and two weeks later was healed over entirely

On examining the pus with a lens, small particles of cotton fibre could be seen in it, showing that the cotton graft not only stimulates granulation, but also acts as a support to it, and, after serving its purpose, is carried away by the pus

UTERINE FIBROMA, WITH REPORT OF CASE

Read before the Section on Obstetrics and Gynecology, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY J H VAN EMAN, M D,

PROFESSOR OF CLINICAL MEDICINE IN THE KANSAS CITY MEDICAL COLLEGE

The subject of fibroid tumors, of the uterus, having been treated of *in extenso* in numerous classical works and monographs, it is not necessary for me, in this paper, to enter either into the etiology, pathology, or diagnosis In the line of treatment I shall say nothing of that by drugs, only speaking of one plan of treatment, viz, removal of both ovaries for the purpose of arresting the growth of the tumors

Our management of cases being largly the result of the accumulated experience of physicians past and present, I shall omit all theory, and simply attempt to add my mite to the general sum of our knowledge on the subject In order to accomplish this purpose, I have the honor to report the following case

Mrs M H, 34 years old, married sixteen years, never pregnant, *has had poor health for twelve years* For seven years has had almost constant sanguineous discharge from the uterus, during the menstrual periods being very profuse In the last two years her physician has five times removed by means of the serrated spoon, a mass of fibroid tissue from within the uterus almost as large as a small goose egg, the growth persistently returning within three or four months after its removal

October 19, 1886 *Examination* —Patient a medium sized woman General condition fair Uterus in position in the median line Length of canal a little more than four inches Fundus above the superior strait From the os, a reddish tumor projected fully one inch Vaginal discharge, bloody and offensive In the left inguinal region, a slightly mobile mass larger than a hen's egg was readily distinguished through the abdominal wall After a thorough explanation of the probable and possible results, she consented to a laparotomy, which was made on October 20, at the patient's home, a little two roomed box house on the open prairie The tumor on the left side proved to be an ovarian cyst Uterus very much enlarged, and showed on its surface, at least two sub peritoneal fibroids Right ovary healthy Two small par-ovarian cysts on that side Ovaries and Fallopian tubes removed on both sides, pedicles dropped, and incision closed

Without going into tedious details, the history, in brief, is, that the highest pulse and temperature occurred at the end of the first 36 hours, viz, pulse 108, temperature 102°, dropping by the end of the second day to 95° and 100° From this time to the fifth day, when the sutures were removed, the pulse ranged from 85 to 90, and the temperature from 99° to 100° The convalescence went on with no complication worthy of mention

The uterine hæmorrhage continued with varying severity, and with increased putridity, until the middle of January, 1887, when after 24 hours of *severe* labor, a large stinking fleshy mass was expelled from the uterus

The further progress of the case I will give by quoting from a letter received from the patient a few weeks since

"I have not menstruated for about two months I was not *very* bad when I menstruated the last time I weigh more than I ever did in my life I appreciate good health, and haven't language to express my feelings "

MEDICAL PROGRESS.

PROPOSED CHEMICAL LUNG TEST —DR ZALESKI, of the Dorpat Physiological Institute, has published in the *Vrach* (No 32) an account of some researches he has been making with the object of introducing a new lung test, which may be trusted to give satisfactory results in cases where the hydrostatic test is inapplicable or of doubtful value He suggests that, as at the moment of birth there is not only an influx of air into the lungs, but a very marked increase in the blood circulating through them, and as blood contains in a tolerably definite proportion, the quantity of iron found in the lungs should furnish a clue to the question as to whether the child had breathed or not He examined the lungs of four stillborn children and of three children born alive, also those of a healthy man who had been killed by an accident Having of course taken care that the lungs had not been subjected to any previous section or manipulation, he tied the roots and cut off the bronchi They were then immersed in distilled water for the hydrostatic test, and, after being dried with filtering paper, they were weighed in a platinum dish, and sections were made and carefully examined After this they were dried in a hot air chamber at from 115° to 120° C until they ceased to lose weight Soda was added to the dried lung substance, also water, and the whole was dried in a water bath The mass was then ignited in a Bunsen's burner, treated with water, and thrown on a filter, which gave no ash The whole was then again ignited Here, all the iron was, of course, not in the filtrate It was then heated with strong hydrochloric acid in a water bath After the hydrochloric acid had evaporated, the residue was treated with sulphuric acid, reduced by zinc, and the iron estimated by a solution of permanganate - The result of the observations showed that the iron contained in the lungs of children that had breathed was always considerably more in proportion to their weight than in the lungs of stillborn children The mean percentage of iron (Fe) in the lungs of the stillborn was 0 0110 of the weight of the fresh lung, and 0 0828 of that of the dried lung, whereas the mean percentage of iron in the lungs of the children who had been born alive was 0 0188 of the weight of the fresh lung, and 0 1182 of that of the dried lung The iron in the case of the adult was still more than in that of the infants, the percentages being 0 0217 and 0 1266 of the fresh and dried lung substance respectively In one case in which the child had lived for five days part of the left lung was found diseased, there being evidences of septic pleuritis and pneumonia Here the diseased portion of the lung was separately examined, and found to contain a percentage of 0 0192 of iron in the fresh state, and of 0 1197 in the dry state, so that it would appear that the "iron lung test" holds good even for diseased lungs The author has not made observations in cases where there has been profuse hæmorrhage from the cord, nor in those where putrefaction has commenced, but he thinks it probable that the test would answer here as well as when the lungs have been immersed in spirit Of course, artificial inflation after death would not vitiate the test, as was indeed proved by one of the cases where Schultze's method of inflation was adopted five hours after stillbirth Dr Zaleski's "iron lung test" is evidently of too complicated a nature to be carried out by the ordinary practitioner, but in doubtful cases it would be quite practicable to preserve the lungs and send them to an expert, just as the stomach and other viscera are sent in poisoning cases Before, however, any real value can attach to evidence deduced from it, a large number of experiments must be made by different observers, and their results collated —*Lancet*, Oct 15, 1887

ANTIFEBRIN IN TYPHOID FEVER —J SOLIS COHEN says The alleged superiority of antifebrin over antipyrin in reducing excessive temperature without injury, led me to employ it during my present term of service in the German Hospital The few attempts made to reduce high temperature in enteric fever present it as a much more dangerous agent than I have found antipyrin to be in a very extensive experience with that agent So powerful an agent has antifebrin proved in the few cases in which I have used it that, as will be seen, 3 grains, or even 1, will effect very decided results on temperature The inference is that small doses should be prescribed, say 3 grains, and that the patient should be visited at the end of an hour and examined as to the reduction of temperature before a second dose is administered, similar precautions being taken as to ordering a third dose, and that when the influence is seen to be marked, subsequent doses should not exceed 1 grain The dose usually recommended has been 8 grains This has been far too large in my hands

Temperature records are appended, illustrating the effect of antifebrin, and showing a remarkable and rapid return of high temperature after initial reduction, with subsequent reduction, and rebound next day without further administration of the drug

I append notes of the effects of antifebrin, manufactured by Merck, on cases of enteric fever

Case 1 —Boy, æt 17 Ninth day of disease, temp 103 6°, 7 grains antifebrin given and repeated in one hour Effect first day of antifebrin, 6 P M, temp 103 2°, 8 P M, 98°, 9 P M, 96 4° 12 midnight, 97° Second day, 4 A M, 102 6°, 6 A M, 103°, 8 A M, 103°, 9 P M, 99°, 10 P M, 97 4° Third day, 2 A M, 102 2°, 7 A M, 102 8°, 7 P M, 104 8°, 5 grains antifebrin given, 8 P M, 101 2°, 10 P M, 99°, 12 midnight, 101 6° Fourth day, 4 A M, 104 2°, 8 A M, 102 8°, 7 P M, 103 8, 3 grains antifebrin given, 10 P M, 98°, 12 midnight, 98 4° Fifth day, 4 A M, 104 8°, 7 A M, 101 2° Orders to discontinue antifebrin and resume routine treatment of the ward

Case 2 —Married woman, æt 22 Fourth day of disease, evening temp 100 4°, fifth day, first day of antifebrin, 7 P M, temp 103°, 3 grains of antifebrin given, 8 P M, 98°, 10 P M, 96° Second day, 2 A M, 98°, 4 A M, 95°, 6 A M, 98°, 8 A M, 102°, 7 P M, 99° Third day, 8 A M, 96 6°, 8 P M, 103 8°, 1 grain antifebrin given, 9 P M, 99°, 12 midnight,

98° Fourth day, 4 A M , 99°, 7 A M , 103 ° 5 P M , 103° Fifth day, 6 A M , 98°, 5 P M , 100°

Case 3 —Boy, æt 19 Temp 5 P M , 103°, 5 grains antifebrin given, 8 P M , 101 4°, 9 P M , 100°, 10 P M , 97 6° Second day, 2 A M , 99 2°, 7 A M , 99 8° 7 P M , 102 8° Third day, 7 A M , 100°, 5 P M , 102 6°

Case 4 —This was a case of so called recurrent typhoid, reentering the hospital, 7 P M , 104 8°, 3 grains antifebrin given, 10 P M , 100 2°, 12 midnight, 103 2 Second day, 4 A M , 102°, 7 A M , 103 8°, 5 P M , 103 6°

Case 5 —Temp 8 P M , 104 2°, 1 grain of antifebrin given, 10 P M , 104°, 12 midnight, 104°, 2 grains antifebrin given, 2 A M , 102 8°, 8 A M , 102 8°, 5 P M , 102° —*Medical News*, October 8, 1887

Chloride of Ammonium in Hepatic Disease —Surgeon General W Stewart says The following is a summary of the auxiliary treatment, diet, and management of congestion of the liver, and mode of administering the ammonium chloride

Bearing in mind what has been said of the therapeutic effects of the drug in hyperæmia of the liver, and the indications to be drawn from the symptoms and pathology of the disease, the first thing to be done is to put the patient to bed, there to remain, in acute cases, during the whole course of the disease, in short, till the congestion, pain, and general and local distress and uneasiness shall have subsided, and that the patient may have no occasion to quit his bed, a bed-pan and urinal should always be at hand, as well as a trusty attendant to minister to his wants By the recumbent position and the avoidance of all sudden and violent movements, mechanical rest and support are given to the enlarged, weighty, and oppressed or painful organ The horizontal position, too, facilitates the auto transfusion of the blood from the portal system, through the hepatic capillaries, into the general circulation, under the influence of our special remedy—a process which will be better understood now that the reader is in possession of the details of the local signs expressive of the effects produced by it the excitation of the muscles of the intestinal canal to increased peristalsis, and those of the abdomen and thorax surrounding the liver to tonic contractions, by which muscular pressure is brought to bear on the radicals of the portal vein, and on the liver and gall bladder, which not only hastens forward the entire portal stream, but may squeeze out of the liver some of the superfluous blood as well as free it and the gall bladder from retained bile By the increase of the functional activity of the liver, as well as the increased flow of blood to the skin, as a further result of its action, a *vis a fronte* is brought into play in aid of the *vis a tergo* above described, by which the equilibrium of the entire circulation is speedily restored The free perspiration induced by the drug is also promoted and chills avoided by the rest and warmth of bed I have shown elsewhere that it is to this latter stage of its operation that much of its value is due—the free diaphoresis favors sleep, while the nervous system generally is exhilarated and soothed, and the patient almost entirely relieved from all distressing symptoms

It is equally important that the congested (or it may be, inflamed) liver should enjoy, as far as possible, physiological rest To this end, on no account must solid food be given to the patient, and wine, beer, or other alcoholic stimulants must be strictly prohibited The diet must be of the least irritating character, and only small quantities of milk, beef tea, or farinaceous articles should be taken at a time Barley water may be taken freely as a drink If there be diarrhœa, the patient passing frequent loose bilious or dark colored motions, a pill composed of two grains of mercury and three grains of Dover's powders, repeated every two hours till four or five have been taken, will be found the most effectual means of checking it without the risk of setting up gastro intestinal irritation Looseness of the bowels, however, does not contra indicate the use of the chloride of ammonium—indeed, it is in itself the best remedy in cases of diarrhœa associated with hepatic congestion The only condition which contra indicates the immediate use of the drug in acute cases is the existence of a combined hot and dry state of the skin with pyrexia Under such circumstances its use should be preceded by a few small and frequently repeated doses of acetate of ammonia, till the skin is rendered moist and perspirable Pyrexia being absent—or, if present, the skin being soft and perspirable,—the chloride should be at once commenced and persistently administered in doses of twenty grains twice or thrice daily, with strict attention to the rules above laid down as to diet, rest, etc , till it no longer produces sensible effects, or till all local uneasiness, hepatic pain, and tenderness have subsided Fomentations or hot bran bags applied to the seat of pain in the side will be of use in aiding determination to the skin generally, as well as by their local soothing effects —*Lancet*, Oct 22, 1887

Treatment of Diphtheria —Mr E Stanley Smith says Recently published memoranda suggest the following notes Gargling in diphtheria, as in all acutely inflamed conditions of the throat, is surely to be avoided if possible Physiological rest for inflamed parts is usually regarded as a cardinal point in therapeutics, the act of gargling involves violent exertion of the muscular apparatus of the fauces and palate, the routine prescription of a gargle frequently causes patients great suffering, and may, I believe, do absolute harm There are few, if any cases in which all the benefits of topical application are not obtainable by either painting, inhaling, or spray

There is nothing new or original in my ordinary treatment of diphtheria, but as it has been very successful, I may be excused for describing it Upon first seeing a case I order salicylic acid, 10 to 20 grains, suspended by means of mucilage in ½ ounce or an ounce of water, to be taken every two to four hours, if there is much pain, I combine 5 to 10 minims of succus belladonnæ with each dose In severe cases I give also a mixture of perchloride of iron and quinine, usually one dose after every two of salicylic acid The acid has answered better than salicylate of soda, especially because, being suspended in mu-

cilage, it adheres to the inflamed surface as it is swallowed, and in mild cases serves all the requirements of a topical application, there is often a little vomiting after the first dose or two, but that soon passes off In all cases, except the mildest, one of the following applications has always served me well, namely 1 Inhalation of eucalyptus oil, 10 drops to ½ pint of hot water, inhaled for five minutes every hour or two 2 Spray of sulphurous acid, diluted with about twice its bulk of water, the acid should be freshly prepared, as evidenced by its pungency 3 Spray of chlorinated soda solution, 1 part of the *B P* solution, with 3 or 4 of water

Whichever spray is used should be applied most assiduously, as often as every hour at first, and it is essential that its administration should be supervised by a thoroughly skilled person, in cases where the upper part of the fauces or the nares are involved the spray should be separately applied to both throat and nostrils

With young or intractable children, inhaling may be managed by means of a bronchitis kettle, and spraying by a large spray-producer—a steam spray answers best—placed at a sufficient distance to ensure its saturating the child's immediate atmosphere

The remarkable restorative powers of Warburg's tincture were well shown in one case of severe nasal diphtheria, in a child about 4 years old The acute inflammatory condition had subsided, there was not much membrane left, the temperature had dropped, the heart's power was decidedly flagging, in fact, the child appeared to be dying from blood-poisoning and exhaustion He was given 10 drops of Warburg's tincture every two hours He soon began to mend, and, after about six doses, rallied so much as to be practically out of danger

Finally, I think that diphtheria, perhaps more than any other acute disease, calls for free alcoholic stimulation, and the most nutritious possible diet from the very first —*British Med Journal*, October 22, 1887

SURGICAL TUBERCULOSIS — *Tuberculosis of the Genito-urinary System* is the third division of Volkmann's article (see the two preceding numbers of THE JOURNAL)

13 Tuberculosis of the *testicle* is prevalent in younger and more mature age, but is found even in very advanced age There is, however, in old people also, a simple, suppurating chronic orchitis and epididymitis that is to be distinguished from the tuberculous form After tuberculous disease of one testicle the other is often attacked later But even in the gravest cases, in which the epididymis has already undergone cheesy degeneration and been destroyed, the testicle itself is penetrated by densely packed miliary tubercles, and after removal of the testicle the patients not infrequently remain perfectly healthy for many years, and do not get tuberculous foci in the lungs or other organs It is therefore desirable, particularly in younger persons, to castrate as early as possible, and before the cord is diseased and the process finds its way to the prostate and bladder, not losing time in making partial resections, scraping, and cauterizing Such conservative and expectant methods are rather to be recommended in the more benign cases of older people

The *secondary affection of the spermatic cord* is manifested partly as an even thickening, and partly in the form of separate wheat grain-shaped swellings in the course of the vas deferens

14 *Tuberculosis of the bladder, ureters and kidneys* is characterized as one of the most typical and grave of tuberculous affections Even in cases in which the process was localized in the bladder it is probable that cure has not been observed The demonstration of tubercle bacilli in the urine will make an earlier and more certain diagnosis possible Whether, in tuberculosis of the pelvis of the kidney, operative interference, nephrotomy and nephrectomy, will be of real value to the patients, has yet to be decided

15 In regard to *tuberculosis of the vagina and uterus* I have not sufficient experience Such cases will more probably come into the hands of gynecologists

16 *Tuberculosis of the mamma* is exceedingly rare, the clinical diagnosis is probably possible only in the later stages The treatment must be amputation, and cleaning out of the axilla, since the lymph channels in the axilla are generally affected early It is important to know that chronic indurated (not suppurating) mastitis sometimes causes swelling of the axillary lymphatics, that later become tuberculous and grow to cheesy gland convolutes as large as the fist, without the mammary gland itself having become tuberculous —*Langenbeck's Archiv*, Bd XXXIII, Hft 1

SUTURE OF THE BLADDER —The *Deutsche Medizinal-Zeitung* summarizes a recent article by DR A BRENNER, an assistant at Billroth's clinic, published in the *Archiv fur Chirurgie*, by which it appears that the author appreciates the force of Guyon's remark that the bladder should be sutured hermetically or not at all. In the method that he suggests, which as yet he has carried out only on the cadaver and in the case of dogs, two threads are carried around the wound, at the distance of an inch or less from it, one running in the submucous tissue, and the other in the muscular coat, care being taken that neither shall involve the mucous membrane Both are then tightened and securely tied The result of this is to form a rosette like pouch, which slightly alters the shape of the bladder, but the wound is made water-tight and air tight —*N Y Med Journal*, Oct 22, 1887

PHTHALATE OF MORPHIA, as compared with other salts of this drug, BOMBELON claims to be highly serviceable It is soluble in 5 parts of water, and causes no irritation when injected subcutaneously It is obtained by evaporation and scaling, not by crystallization, and care is necessary in its preparation

COUMARIN AND IODOFORM, says A LANGLEBART, is a combination in which the odor of iodoform is disguised and its antiseptic properties increased He used about 1 part of coumarin to 5 parts of iodoform

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE INCLUDING POSTAGE

PER ANNUM, IN ADVANCE $5 00
SINGLE COPIES 10 CENTS

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

THE TREATMENT OF FRACTURES OF THE OLECRANON

The cure of fractures of the olecranon, as is well known, is almost always brought about by a fibrous callus, more or less long and resistant, which, in the greater number of cases, restricts the movements of the forearm to a marked degree, and the functional result is often bad The cause lies in the difficulty in making and maintaining complete coaptation of the bony fragments The old surgeons, with the idea that anchylosis of the elbow generally takes place, placed the forearm in a position of semi flexion In this position the separation of the fragments is considerable, and consolidation takes place only by means of a long and thin fibrous band This method of treatment has now been abandoned for moderate or even complete extension Anchylosis or articular stiffness does not depend, in fact, on the position given to the limb, but on prolonged immobilization of the joint

The more rational idea, says M FRAIPONT in a recent article on this subject in the *Annales de la Societe Medico Chirurgicale de Liege*, is to place the forearm in a position which permits the better approximation of the bony fragments This position is complete extension On the anterior face of the elbow is placed a rigid splint, and the upper fragment of the bone, held up by the triceps, is drawn down by strips of adhesive plaster which pass over the summit of the olecranon and cross the forearm in a spiral The approximation of the bony parts may be done exactly in spare persons, where the fracture is accompanied by only a moderate degree of extravasation, but when blood is extravasated into the joint, especially when the quantity is considerable, coaptation is difficult or impossible Folin advises delay until the swelling has been dispersed by the use of a fixation apparatus But for this 8 or 10 days are necessary, and then it is too late to hope for bony union, even if we can succeed in placing the upper fragment against the body of the bone, for the blood between the fragments has had time to begin fibrous organization, and the new tissues play the part of foreign bodies which hinder consolidation Lauenstein two years ago proposed to treat fractures of the olecranon by Volkmann and Schede's method for fractures of the patella—antiseptic puncture of the joint by means of a large trocar, removing as much as possible of the extravasation, which is the great obstacle to coaptation, and then approximate the fragments by adhesive strips, the forearm being fixed in complete extension by means of an anterior splint He has reported two cases in which this method was successfully used, but it must be said that in these cases the patients came under treatment immediately after the injury, and before the blood had time to coagulate But coagulation soon takes place—a few hours after the fracture—and the mass is then too solid to be removed by a trocar, in such cases puncture is useless, and may be dangerous despite antisepsis, on account of the blood clots in the tissues

In a criticism on Lauenstein's article two years ago, Fraipont expressed the opinion that it would be possible in fractures of the olecranon, as in those of the patella, to practice metallic bony suture, after having carefully and antiseptically cleansed the articulation and the peri articular tissues, and last April he had an opportunity of carrying out this idea in the case of a woman, 44 years old, who had sustained a comminuted fracture of the olecranon, the upper fragment being in several pieces There was very great swelling of the elbow, so much so that the joint had assumed a cylindrical shape, and was filled with blood clots, which crepitated on pressure Under such circumstances puncture of the joint could have evacuated only what fluid there was in the joint—at best a very small quantity—and it was decided to practice metallic suture The operation was done after the most minute antiseptic precautions had been taken, in narcosis, and after an Esmarch's bandage had been applied to the upper part of the arm A longitudinal incision 12 centimetres long was made at the middle of the posterior surface of the elbow, taking in the seat of the fracture The intervals between the fragments were filled with clots of blood, black, resistant, and firmly

adherent to the bone, so that they had to be removed with a curette Similar clots were found under the skin and in all the peri-articular tissues, and a few in the joint itself, but there was very little fluid blood The cleansing was made with the greatest care, and under almost continuous irrigation with a 1 per cent solution of corrosive sublimate The fracture was transverse, and the upper fragment was divided into three pieces, a median and two small lateral, which were adherent to the fibrous tissues surrounding them The fragments were brought together and fitted by means of a single metallic suture, which passed through the three pieces, then through the upper part of the ulna, the articular surfaces being avoided The forearm was placed in forced extension The silver suture was perfectly twisted and flattened on the bone The articular capsule, torn from right to left, was then sewn up with silk, and the skin was then united by means of deep and superficial sutures No apparatus for drainage was applied The joint was then covered with a dry iodoform and other dressing

The patient left the hospital on the fourth day, having had no general reaction whatever She returned on the fifteenth day in excellent condition, when the extension apparatus and the dressings were removed There was no trace of local reaction or of swelling, and the wound had healed by first intention The sutures were removed, and after applying a layer of iodoformized collodion over the line of suture the forearm was placed in a position of moderate flexion on the arm, and fixed in this position by means of a plaster apparatus Five weeks after the injury the second and last dressing was removed, and bony union was found to be complete Tepid baths, massage and passive movements were then begun, and in three weeks the woman had perfect use of her arm, she made all the movements of the forearm with ease

TREPHINING IN EPILEPSY

DR W B FLETCHER, Superintendent of the Indiana Hospital for the Insane, Indianapolis, reports, in the *American Journal of Insanity*, October, 1887, 8 cases of trephining for traumatic epilepsy In these cases insanity did not occur at or near the time of the injury, but some years afterwards In 3 cases epilepsy preceded the insanity, but remote from the time of the injury In all but one (and in that case the injury was most extensive in appearance) very strong adhesions to the dura were found All the patients were, at the time of the operation, melancholic, suicidal, profane, and 4 destructive to clothing, none are so now

"I believe," says Dr Fletcher, "that in traumatic injury, in which sunstroke is included by most authorities, the pain and reflex nervous affections most frequently arise from the inflamed and adherent dura, at points where one of the three sensory branches of the fifth nerve is involved In none of these cases do I think the cortex had undergone any pathological change"

In two cases it was noticed that in tearing up the adhesions the face, platysma and fingers on the same side were convulsed, while a probe passed freely upon and into the convolutions without causing visible sign of excitement It would be comparatively easy, says the author, to locate most injuries and diseases of the cerebrum, were it not for the complicated nervous connection of the dura mater As Duret says "Their varied and, so to speak, protean manifestations tend at each step to complicate the whole symptomatology by superimposing themselves in the phenomena due to lesions of the nerve centres proper" More than this, every one knows that cicatrices of the scalp from old wounds often give the impression of depressed bone They are often sites of acute pain, may cause insanity, and partial paralysis and convulsions, from the fact that the dural branches of the fifth nerve are involved in the external cicatrices

In view of the fact that insanity so often follows fracture and depression of the skull, Dr Fletcher is inclined to inculcate the doctrines of Hunter regarding injuries of the head "As we cannot tell for certain at the time whether the symptoms arise from concussion, compression or extravasation of blood, it may be more advisable to trephine, as the operation can do no harm" That it is a safe procedure to make exploratory openings into the skull, through the dura, and tap the cortical substance with a probe or probe-pointed needle, most surgeons will readily admit And there is probably a great deal of force in Dr Fletcher's remark, that more surgical treatment in our hospitals for the insane would add to our percentage of cures

THE DEATH OF DR GUNN

MOSES GUNN, A M, M D, LL D, died at his residence in this city November 4, after several months of suffering from malignant disease of the stomach He was born in East Bloomfield, Ontario Co, New York, April, 1822, received a fair academic education in the schools of his native town, and in 1846

received the degree of M D at the Geneva Medical College, Geneva, N Y He commenced practice the same year in Ann Arbor, Michigan, and in addition to ordinary practice, he commenced giving instruction in anatomy to such students and practitioners as chose to attend his lectures

In 1849 the State University of Michigan, located at Ann Arbor, organized a Department of Medicine and Surgery, and Dr Gunn was appointed to the Professorship of Anatomy and Surgery, and commenced his first regular course in October, 1850 In 1854, he relinquished the course in anatomy, and restricted his teaching to surgery exclusively in the University until 1867 In the spring of that year he accepted an invitation to fill the Professorship of Surgery in the Rush Medical College in Chicago, made vacant by the death of Prof Daniel Brainard in October, 1866, and removed his residence to that city, where he entered upon the general practice of surgery and continued to fulfil the duties of his professorship until the close of the college term of 1886–7 During the seventeen years of his connection with the Michigan University, and the twenty subsequently with the Rush Medical College, Professor Gunn won and maintained a high reputation as a practical surgeon, a popular teacher, and a man of honor By his death, the College Faculty has lost one of the oldest and strongest of its members, and the community one of its most kind and skilful surgeons

THE CROWN PRINCE AGAIN IN DANGER

LONDON, Nov 7 —Dr Mackenzie, who has been suddenly summoned to San Remo to attend the Crown Prince of Germany, telegraphs to night "There is a recurrence of the growth lower down I am issuing unfavorable bulletins to night " It is thought here that it will be necessary for the patient to undergo another operation

BERLIN, Nov 7 —Drs Schroerer and Krause have been ordered to San Remo to consult with the English physician Prince William, son of the Crown Prince, also leaves for San Remo to night

PEDDLING AND PRESCRIBING GLASSES —DRS L WEBSTER FOX and G M GOULD have recently made a very timely and sensible plea for a law restraining peddlers, jewellers and opticians from prescribing glasses They cite many cases of injury, often permanent, to eyes from errors due to ignorance, and claim that such "opticians" should be as much under legal restraint as druggists

THE BRAINS OF THE INSANE —POGGI, says the *American Journal of Psychology*, examined the cerebral convolutions of fifty brains of the insane, and found anomalies more common than in the sane, especially in the left hemisphere The most frequent anomaly is a double calcarine fissure, or communication between the internal occipito parietal fissure and the sulci of the cuneiform lobule—30 per cent The brains of the insane are particularly characterized by numerous anastomotic folds

THE MEDICAL INVESTIGATOR —Dr S P Smith, of Louisville, Ky, proposes to publish a 24 page weekly, *temperance medical journal*, with this title, commencing on the first Wednesday in January, 1888, price $2 per annum We wish him and his journal abundant success

THE J B LIPPINCOTT COMPANY, publishers of *The Archives of Pediatrics*, edited by W P Watson, M D, announce that in the issue of the January number, 1888, will begin a series of articles on the "Therapeutics of Infancy and Childhood," by Prof A Jacobi, of New York

THE AMERICAN JOURNAL OF PSYCHOLOGY is the title of a quarterly journal the first number of which has just appeared It is edited by Professor G Stanley Hall, of Johns Hopkins University Its object is to record psychological work of a scientific, as distinct from a speculative character

NEW YORK STATE MEDICAL ASSOCIATION —The fifth special meeting of the Fifth District Branch will be held in the Pavilion Hotel, New Brighton, Staten Island, at 1 P M on Tuesday, November 15, 1887

SOCIETY PROCEEDINGS

MEDICAL SOCIETY OF VIRGINIA

Eighteenth Annual Meeting, held in Richmond, October 18, 19, 20 and 21, 1887

FIRST DAY

The Eighteenth Annual Session of the Medical Society of Virginia convened in the Capitol Building in the city of Richmond, Va, Tuesday night, 8 o'clock, October 18 A very large audience of ladies and gentlemen, not doctors, was present to witness the opening of the session The session was called to order by the President, DR BEDFORD BROWN, of Alexandria, Va After prayer by Rev S S Lambeth, of one of the Methodist churches in this

city, DR THOS J MOORE delivered the *Address of Welcome*.

THE PRESIDENT then introduced DR WM S CHRISTIAN, of Urbanna, Middlesex County, Va., who delivered the *Address to the Public and Profession*, and announced as his subject

SOME OF THE DIFFICULTIES IN THE WAY OF THE SUCCESSFUL PRACTICE OF MEDICINE

He classified the difficulties as either those that necessarily belong to the profession of medicine, and into those incidental thereto or produced by persons and things outside of the profession

DR WM D TURNER, of Fergusson's Wharf, Va., as chairman of the committee on nominations, presented a list of

SEVENTY-THREE APPLICANTS FOR FELLOWSHIP,

which the committee had approved, and on motion the gentlemen were elected Fellows

---

WEDNESDAY, OCTOBER 19—SECOND DAY

After the usual routine proceedings of organization, Vice-President Dr Alex Harris, of Jeffersonton, was invited to assume the Chair

THE PRESIDENT, DR BEDFORD BROWN, of Alexander, then delivered the *Address of the President* His subject was

THE ADVANTAGES OF THE PRACTICAL STUDY OF MEDICAL SCIENCE AS A MEANS OF PROMOTING PROFESSIONAL SUCCESS

The proposition contained in the title was well sustained by facts and logical deductions

The next order of business being the discussion of the regularly selected subject, the appointed leader of the discussion, DR HUNTER MCGUIRE, of Richmond, read a paper on

THE CHOICE OF GENERAL ANÆSTHETICS

(See page 619)

On invitation by the President, DR WILLIAM A HAMMOND, of New York, said that while listening to the paper of Dr McGuire, he felt that he was sitting at the feet of a master And yet as he had had experience with both ether and chloroform, especially while a surgeon in the U S Army years ago, he felt that he had a right to an opinion on the subject under discussion, which he would take the liberty of expressing.

He had been one of the unfortunates who had witnessed two deaths from the surgical use of chloroform His first fatal case occurred about thirty-five years ago while he was serving as an assistant surgeon in the U S Army, out on the frontiers A dragoon had been drunk, and had very seriously hurt his arm He did not see the dragoon until about two weeks afterwards He then undertook to examine the injury by first placing the patient under chloroform Just as he was getting under the influence of the anæsthetic, the dragoon died *suddenly*

Previous to the administration, there was nothing to indicate that he could not take chloroform But upon post-mortem examination when his heart was taken out, and cut up into minute sections, and placed under the microscope, that organ was found to be undergoing fatty degeneration This condition could not have been recognized by the naked eye—it required the microscope to detect it Nor was the morbid condition sufficiently far advanced to allow of its diagnosis by physical signs or any of the usual symptoms of advanced fatty degeneration There is no way known to him by which such cases can be foretold, and yet he could not resist the conclusion that the fatty heart was the cause of that dragoon's death There was nothing else to possibly account for it The case was reported at the time in the *American Journal of Medical Sciences* The chloroform was carefully examined, and found to be good

The second case of death by chloroform under his observation occurred in Virginia Just after the memorable battle near Fredericksburg, during the late war, a soldier was brought in who needed exsection of the elbow The circumstances of the battle made it desirable that he "should be a little in in a hurry" Just as he was picking up his knife to begin the operation, the soldier died *suddenly*—without a moment's warning, exactly as Dr McGuire had described his case as dying Since then, he has not used chloroform much, but has adopted ether in preference Whether he had had remote deaths or not from the use of ether, he does not pretend to say—especially after what Dr McGuire has said about the more than possible after effects of its administration But this he has to say, that he has never been horrified by a sudden death while using it In fact, he does not think that he has ever had any bad effects from the use of ether He wishes he thought chloroform as safe to use as ether, for undoubtedly chloroform is much more agreeable both to the patient and administrator He wishes he could make more emphatic than Dr McGuire has already done, the great importance of not being in a hurry when about to give chloroform For army uses, ether he thinks, is unquestionably to be preferred

As to how these anæsthetics kill, he is unable to satisfactorily explain Chloroform undoubtedly kills by stopping the heart's action in the majority of cases, but why, he does not know As to ether, its immediate dangers are so much less than chloroform that he prefers it As to the after effects of this agent, Dr McGuire is most probably correct in saying that deaths are due to it that are not attributed to it in the mortuary tables

Some years ago a Frenchman proposed venous injection of chloral hydrate The anæsthesia lasts from seven to eight hours Dr Hammond has adopted this anæsthetic in only one case It was a case in which he determined to stretch the sciatic nerve He injected a solution of chloral containing 7 grains of chloral into the cellular tissue, instead of making it intra-venous Anæsthesia followed in a few minutes and lasted five hours, with sleep, most if not all the time The nerve was stretched according to the usual method without any sensation of pain

Another good anæsthetic is *hypnotism*, but this is liable to much abuse in the hands of charlatans The patient hypnotized is not absolutely insensible, but the cutting of the surgeon cannot be said to be painful It does not seem that more than about one in five or six are proper subjects for hypnotism, and it cannot well be determined who are fit subjects until the experiment is made upon the individual The process is not due to the party who operates, but to the susceptibility of the person to be acted upon

Dr George H Rohe, of Baltimore, Md, an invited guest, said he was much pleased with the fair manner in which Dr McGuire had opened the discussion As to the danger of paralysis of the heart during chloroform administration, he thought the proper explanation might be that given by Brunton Chloroform paralyzes the vaso motor centres, while, during ether narcosis, the vaso motor centres continue active for a much greater length of time As to the rarity of deaths from chloroform given during labor, he thought Barnes' explanation a satisfactory one It is that during gestation, the heart undergoes a conservative hypertrophy, and hence has greater power to resist the paralyzing influence of chloroform This condition of the heart does not occur usually in cases that are brought to the attention of the surgeon for operation Generally speaking, in such cases, the disease or injury demanding the use of the surgeon's knife is such as to impair the tone of the heart, either for the time or permanently In surgical cases, also, the dread of the anæsthetic or the manner of its administration acts as a shock to the nervous system As to the prevalent opinion about the immunity of children from the dangers of chloroform, as remarked upon by Dr McGuire, Dr Rohé quoted from authorities to show that about one in ten of all deaths from chloroform occur in children under 12 years of age He thought, also, that Dr McGuire's statistics could stand correction as to the stage of the administration when the greatest danger presented He referred to authorities to show that about one half of all fatal cases from chloroform occurred either during the surgical operation or else immediately afterwards He believed it to be good doctrine to always advise the administration beforehand of a suitable dose of atropia with morphia This combination maintains anæsthesia, while it, at the same time, keeps up the activity of the vaso motor centres He agrees with Nussbaum in objecting to the use of ether before beginning with chloroform There have been two deaths from chloroform in Baltimore during the last two years He has given ether in the manner that Dr McGuire opposes But he has never seen the depressing effects upon the heart, but upon the respiratory organs To sum up, he believes ether safer than chloroform in the large majority of cases

Dr Herbert N Nash, of Norfolk, Va, said he has now changed his preference from chloroform to ether when an operation is to last over half an hour He believes chloroform kills chiefly by depriving the nervous centres of the requisite amount of oxygen He has seen distressing effects come from ether Contrary to Dr McGuire's opinion, he thinks the presence of pain has an influence in overcoming the paralyzing influence of chloroform In children, his experience has confirmed the preference expressed by Dr McGuire for chloroform

Dr J S Wellford, of Richmond, Va, said that during his service as surgeon in the Confederate Army, he could not get ether as freely as he wanted it, and hence had to use chloroform, and one death came under his observation That death was probably due to methylated chloroform, received from England Methylated chloroform is cheaper than ethylated The purity of the chloroform is, therefore, a very important matter Anxiety on the part of the operator, especially if he be in haste, may cause him to overdo the matter and "crowd" the chloroform so as to cause suffocation Ether is safer under such circumstances because it contains a very large percentage of oxygen Anstie has shown that air containing over 5 per cent of chloroform is dangerous Death has frequently occurred before commencing the operation after the administration of chloroform Given internally, it is a valuable anæsthetic, the full virtues of which use have not been sufficiently dwelt upon by authors Two thirds of the deaths from chloroform have occurred in the dental chair, showing the great danger of administering this agent while the patient is in less than the prone position One, if not the chief, reason why we do not have fatal cases in obstetrical practice is because chloroform is given to allay the suffering from "pains" that throw the blood into the cerebral circulation In surgical cases, there are no pains when the patient is under the influence of the anæsthetic Anstie has shown that the genito anal region and the matrix of the great toe are about the last regions of the body to become anæsthetized Hence operations about these parts require more chloroform than other cases, and hence the great number of deaths that occur from anæsthesia when these parts are to be operated upon The purity of the agent is an important matter, and the manner of administration is just as important Such was the harmlessness of chloroform administrations in the Confederate Army that hospital stewards, even, often gave it The secret was undoubtedly due to the fact that they were taught the importance of having a plenty of fresh air mixed with the chloroform during its administration There is danger in giving chloroform to those whose hearts have been overtaxed, as by alcoholism or prolonged intoxication Ether deaths are frequently attributed to intercurrent pneumonia, and therefore are not put down as deaths from the anæsthetic He ventures to assert that when the true record of deaths by anæsthetics is written up, as many fatalities, if not more, will be found to be due to ether, but they are of secondary occurrence His conclusion is that both ether and chloroform are dangerous, perhaps in about equal ratio Hence do not give either unless there is a clear indication for one or the other

Dr I S Stone, of Lincoln, Va, remarked that for operations requiring only a few moments, he preferred *bromide of ethyl* to ether or chloroform He thinks it much safer than chloroform, and it does not

carry with it the dangers attributed by Dr Wellford to ether

DR ALEX HARRIS, of Jeffersonton, Va, said he had used both ether and chloroform since their popular introduction into the armamentarium of the doctor As he has had no accident from chloroform, and as it is so much more agreeable than ether to give and to take, he saw no reason to surrender his preference for chloroform He always freely admits air during chloroform administrations He is not surprised at the record of deaths from its use by those who give it as they would give ether The agents are entirely different chemically, and call for different methods of administration As a complication of the prolonged or excessive use of chloroform, he has seen jaundice occur

DR J E CHANCELLOR, of the University of Virginia, said he has used, and been a close observer of the use of both the anæsthetics since their introduction He has settled upon the combined use of ether and chloroform as safer than either of the two alone, and says further that the combination acts more quickly He has also used the combination of one-third alcohol and two thirds chloroform, and asked Dr McGuire if he had any experience with such a combination?

DR MCGUIRE said that he had frequently used the "A C and E mixture," but has abandoned it because he gets some of the dangers of *both* ether and chloroform by its use, whereas the danger of either was as much as he is willing to be responsible for

DR CHANCELLOR said he had seen one death under the use of chloroform, but he is unwilling to testify whether the anæsthetic or the shock of injury killed the patient

DR W T OPPENHEIMER, of Richmond, Va, remarked that all cases of ether deaths are by no means recorded He had witnessed two deaths by this agent in New York City One of the cases was in the practice of Dr Keith The ether was being given for the operation of excision of the knee The other case occurred in the practice of Dr Bryant He has since adopted chloroform, and prefers it Chloroform is specially preferable if there is hæmorrhagic diathesis In fact, in a case of hæmorrhage from the lungs, bleeding was several times arrested for three or four hours by the repeated administrations of chlōroform

DR THOMAS R EVANS, of Mt Carbon, West Va, arose principally to say a word for the country doctor He is usually unable to carry around with him more than an ounce or so He has several times derived the desired anæsthesia by giving *chloroform internally* in teaspoonful doses This dose will sometimes anæsthetize for several hours at a time, and by common consent, this practice seems to be less risky to the patient's life He does not know why it is not more generally adopted

DR E W ROWE, of Orange C H, Va, has had no death from either, but has been scared by both, especially when administered soon after eating He inclines to a preference for chloroform, being always careful as to the time and mode of its administration

In answer to questions, DR HAMMOND said he has had no experience with rapid breathing as an anæsthetic, but has known it to cause convulsions simulating those of epilepsy As to chloral, the solution of 7 or 8 grains should be given as different injections in different parts of the body He has had one death from chloral The patient was in the habit of taking 20 grains three times daily After about a year or so of such habit, sudden stupor came on, and he died The exact manner of his death was uncertain

DR WM W PARKER, of Richmond, Va, thinks he was the first doctor in this State to use chloroform after its announcement as an anæsthetic One of his patients years ago had got in the habit of using it to such an extent as to use $3,000 worth in three years' time, and finally died from it Properly given, he thinks chloroform the safer of the two anæsthetics It should not be given from a cone or buttoned shirt cuff or anything else of the kind The safe way of administering it is for the patient to lie down, with clothing perfectly loose and using an open napkin or a suitably shaped sponge This is to be moistened with a few drops of chloroform as often as it evaporates, and held three or four inches above the nose and mouth In this way, all danger of not having enough of fresh air is avoided, and the patient is not overwhelmed, so to speak Exercise a little patience, and all will go well In this way, on one occasion, he gave chloroform almost continually, night and day, for three weeks, without an alarming or a threatening symptom

DR J GRAMMER, of Halifax C H, thought that prominent mention should be made of whiskey as an anæsthetic in such a discussion as this He referred to a case that came under the observation of Dr J Herbert Claiborne, of Petersburg, Va, in which a woman who was drunk passed entirely through all the pangs of labor without the slightest evidence or any after recollection of having had any suffering During the war, many wounded soldiers were operated on without suffering pain—the anæsthetic being whiskey, because of the lack of chloroform

DR W L ROBINSON, of Danville, while generally preferring chloroform, could not agree with Dr Wellford in thinking that the presence of "the pains" was the cause of the exemption of danger in chloroform administrations during labor We have pains of the severest kind in many surgical operations where the patient dies As to the matter of hæmorrhage being checked by chloroform, which has been referred to, he has known hæmorrhages begin in labor, after the use of this agent, which he saw no other way to account for than as a result of the use of chloroform

THE PRESIDENT mentioned a case which came under his immediate care some thirty years ago A boy, aged 17 years, was kicked by a horse, removing a large portion of the frontal bone, and injuring the anterior lobes of the cerebral hemispheres Singularly, the mental condition remained good, but the injury so exposed the brain to view as to allow of excellent opportunities for examination To apply the proper surgical dressings, it was necessary to resort to an anæsthetic to relieve the suffering A

mixture of chloroform and ether was used It was the first case on record where an opportunity was allowed to witness the effect of chloroform, etc , on the brain circulation With each administration of the anæsthetic the brain was seen to become anæmic—almost bloodless The natural pulsations were seen to gradually fade away as the anæsthesia became more and more profound, until finally the brain seemed almost bloodless The observations were repeated six times so as to confirm the fact that the condition was due to the anæsthetics Whether it was the chloroform or the ether that caused this condition of things he does not pretend to say, as neither was used alone

Dr McGuire, in closing the discussion, said that as to the dangerous symptoms that have been observed during the administration of anæsthetics, the profession agrees that ether is not so safe in diseases of the kidneys He had not undertaken the task of writing an exhaustive paper on the subject, but had tried to confine himself chiefly to some mooted points, in the hope of getting light on them He fully agrees with Dr Wellford that the purity of the agent, whether it be ether or chloroform, is a very important matter In dentistry there are two causes of danger One is the upright or only half reclining position in the chair, and the other is the inclination of the dentist to pull the tooth before there is complete anæsthesia Mr Keith, of Edinburgh, has used the Clover bag for ether administration for two hours or more at a time But such a bag for chloroform would be dangerous Dr D Hayes Agnew, of Philadelphia, has been unfortunate enough to recently add another to the death list from ether, and no one who knows his skill and caution can doubt for a moment but that the ether was properly given by him It simply illustrates that anæsthetics are dangerous, and should not be resorted to without sufficient justification for the use of such a powerful agent As a conclusion from his study of the subject, he believes that one anæsthetic is about as dangerous as the other, and that each should be selected on the principle of the special fitness of the subject for one or the other

(*To be concluded*)

CHICAGO GYNÆCOLOGICAL SOCIETY

Regular Meeting, Friday, June 24, 1887

The President, Chas Warrington Earle, M D, in the Chair

(*Concluded from page 604*)

Dr Bayard Holmes read a paper entitled

THE BACTERIOLOGICAL EXAMINATION OF AN EXTRA-UTERINE FŒTUS, AND THEORETICAL CONSIDERATIONS OF THE BACTERIOLOGICAL CONDITION AND FATE OF DEAD, RETAINED FŒTUSES

I These nine tubes of nutrient gelatin containing pieces of the different organs of an extra uterine fœtus was removed by Dr Christian Lenger, in the Milwaukee Hospital, on the 7th of March last The diagnosis of extra uterine pregnancy was made some months previous by Dr Senn, and the subsequent death of the fœtus was recognized by Dr Mickle The vagina had been rendered as sterile as possible before the operation by means of the antiseptic tampon and irrigation The incision in the posterior wall of the vagina was made with Paquelin's cautery, and a way opened between the rectum and vagina with dull instruments The sac about the fœtus was then cut through with the cautery, the short forceps applied to the presenting head, and the fœtus delivered Everything was done under the strictest antiseptic precautions The duration of the operation was about two hours The fœtus presented a very fresh and natural appearance, though it was a little softened It had been dead two months

As soon as the fœtus was delivered it was wrapped in a large piece of carbolized gauze, and conveyed to an adjoining room, where everything was ready for this examination Here the large cavities were quickly opened with the sterilized knife, and pieces of the various organs and their contents removed with instruments sterilized with heat These pieces were put in the liquefied blood serum gelatin, which was then allowed to cool Ten tubes were used in the examination One was unfortunately broken in the laboratory after it had been kept long enough to prove its sterility The culture medium was a 20 per cent solution of gelatin in peptonized beef tea, to which an equal quantity of sterile hydrocele fluid had been added This gave a medium which contained only 10 per cent of gelatin It coagulated if heated above 62° C , but had the advantage of being very nutrient and yet being liquefied by the action of certain bacteria

With one exception all of these tubes are, after almost four months, solid and unchanged One contains a piece of the skin cut from the abdominal wall of the fœtus Within 48 hours after implantation a small, white, liquefying colony was noticed at the side of the little piece of skin Examination showed that it was the *Bacillus subtilis* Now the gelatin is completely liquefied, and rendered turbid by the bacteria which have been mixed with it in transportation and handling There is no doubt but that this was an accidental infection either during or after the operation In the eight solid tubes remaining are some of the hair and sebaceous matter, the brain, an inch of intestine and its contained meconium, a piece of the heart, a piece of the liver, a piece of the lung, one of the phalangeal bones, and one perfectly transparent tube which contains a portion of the fluid from the abdominal cavity

This examination is conclusive evidence that the organs examined were free from any living bacteria or their spores that were capable of growing in the culture medium used If any evidence of the perfectly sterile condition of this fœtus and its membranes were wanting after it had been retained two months subsequent to its death in the abdomen of the mother, this examination would seem to supply that want Could we be certain that the culture

medium used would support the life of all bacteria, nothing more could be desired We may, however, safely assume that this fœtus and its intestinal contents were perfectly sterile

II —During the past ten years, the burden of bacterial research has proven conclusively that the healthy human body is free from all living micro organisms The fate of bacteria introduced into the circulation of healthy animals has received some attention It may be safely said that non-pathogenic bacteria cause no more disturbance than an equal quantity of finely divided, lifeless vegetable matter They are quickly taken up by the white blood-corpuscles, and eliminated by the lymphatic system, or remain imbedded in the reticulum of some of its glands

The pathogenic bacteria also, in some cases at least, meet with a similar fate, being unable to overcome the normal physiological resistance of the healthy host Thus even the *Bacillus anthracis* was shown by Feser to be unable to invade rats that had been fed on flesh, though, after having been restricted to a vegetable diet, the same animals fell easy victims to inoculations Birds, under ordinary conditions, resist inoculations of anthrax Pasteur has shown that this due to the high temperature of the order, which is little below the limit of multiplication of the bacillus in artificial culture media If the temperature of the fowls is reduced two or three degrees by immersing the lower portion of the body in cold water, they become susceptible to inoculations Passet finds that the *Staphylococcus cereus albus* and *flavus* produce no action when injected into the injured subcutaneous tissues of animals, although they produce suppuration in man Max Schuler concluded from his experiments on animals, even before the true bacterial origin of tuberculosis had been demonstrated, that the infection of bones and joints did not take place, as a rule, after injection of tuberculous matter into the circulation, without previous contusion of the selected part, or its irritation by injected chemicals Kœnig arrives at the same conclusion from a clinical consideration of tuberculosis It is probable, therefore, that the bacilli in the circulation are eliminated or destroyed

When pathogenic bacteria are introduced into the blood-current after the mechanical or chemical injury of some selected part, they multiply only at this point of diminished physiological resistance, although their presence can be demonstrated in other parts of the body According to Huber, the *Bacillus anthracis* multiplies entirely within the blood vessels in which stasis has been produced In distant parts of the body, only scattered, single, non-vegetating individuals are found, and these are frequently contained in the reticulum of white blood corpuscles That these scattered bacteria are alive has been shown by Rosenbach in the case of the *Staphylococcus albus* by means of culture methods Huber found the bacteria never passed outside of the blood-vessels into the œdematous or suppurative (?) exudate

The resistance of the blood may be so low that multiplication of the invading microbe takes place in the circulating blood itself Such a condition is clinically termed septicæmia in distinction from sapræmia and pyæmia It usually follows one of these conditions It may, however, be due to the invasion of a peculiarly powerful bacterium, or an unusual susceptibility in the part invaded

Nearly all bacteria, under certain circumstances, resort to a method of development and reproduction called spore formation It begins with the appearance of a very small granule in the protoplasm of a hitherto vegetating cell This granule increases in volume, and becomes a strongly refracting sharply outlined body, which rapidly reaches a definite size, and then represents a perfect spore The spore is always smaller than the mother cell The protoplasm and former contents of the cell disappear in proportion to the growth of the spore Finally, the spore appears in the delicate membrane of the mother cell suspended in a clear, watery fluid only. The causes of spore formation are not yet fully known in all species In some it seems to depend upon the unfavorable condition of the nourishing medium, while in others it bears no relation to vegetation Spores endure vicissitudes of heat and cold and chemical action better than vegetating cells, and also resist the action of staining fluids

It is probable, though, so far as I know, yet undemonstrated, that the pyogenic bacteria leave behind in the cicatricial tissue after suppuration such lasting spores Of this there is abundant clinical evidence in the case of such diseases as pneumonia, rheumatism, osteo-myelitis, and erysipelas In individuals that have once been subjected to an attack of one of these diseases, sudden outbreaks of the long absent disease follow slight causes which tend to produce a diminished physiological resistance

The fate of bacteria in the circulation may be thus summarized

1 They may be wholly destroyed without multiplication

2 They may multiply at one or two points of diminished physiological resistance, and remain only scattered and non-vegetating in other parts of the body

3 They multiply in the general circulation everywhere

4 After localized multiplication, they may produce lasting spores which remain a long time imbedded in the cicatricial residue and, at some later period, under favorable circumstances, these may again germinate and multiply, and give rise to their own peculiar form of inflammation

I recognize the fact that the formation of spores in the living body has yet to be demonstrated, but it seems to me that the clinical evidence is sufficient, when considered with the well known laws of spore formation in exhausted artificial culture media, to warrant this assumption for theoretical purposes

3 When dead animal tissue is introduced into the living animal body, it produces no considerable inflammation A multiplication of the surrounding cell elements takes place, with increased vascularization The dead tissue is invaded, taken up in part by white blood-corpuscles, and carried away There may be a greater or less residue, surrounded by a

mass of cicatricial granulations The neighboring lymphatics may contain portions of the more resist ing and often pigmented residue We see this removal illustrated every day, as Senn has shown in the case of catgut ligatures When they are perfectly antiseptic, they never give rise to any undue inflammation or suppuration Again, the same process is observed in subcutaneous operations, in cerebral hæmorrhage, hæmorrhage about simple fractures, and into the large joints The completeness of absorption depends, in these cases, upon the amount of the hæmorrhage, and the age and nutrition of the individual Suppuration or other unfavorable results take place with extreme infrequency

The fate of a retained, dead fœtus, therefore, whatever its position, must depend almost entirely upon its bacterial condition If it contain no pyogenic or putrefactive bacteria, one would expect it to produce no more inconvenience than would result from its size and weight It may become macerated, mummified, or calcified By pressure atrophy, it may find its way into the intestinal tract It may be discharged with a living fœtus It may later become infected, and give rise to all the serious consequences of suppuration Or, it may be artificially removed

IV —There is little doubt that the living fœtus is free from all micro organisms Leopold put young fœtuses into the abdominal cavities of rabbits under strict antiseptic precautions, and found that they gave rise to no suppuration They were either wholly or partly absorbed, or they remained unchanged, or they were reduced to a small residue resembling lithopedia Had these fœtuses contained any living pyogenic bacteria or their spores, the warmth of the abdomen and the absolute lack of resistance in the dead fœtuses would have resulted in their rapid destruction, and in suppuration in the living tissue about Kuchenmeister has collected a large number of cases in which extra uterine fœtuses have remained in the human abdomen many years, sometimes almost unchanged, and at other times in various states of absorption

Of all parts of the fœtus, the meconium, being itself without possibility of physiological resistance, would be most likely to show the presence of infection Its infection might take place either through previous infection of the amniotic fluid from the mother's circulation, or through infection of the fœtus by way of the placenta The amniotic fluid might be infected more easily than the fœtus, as it has been shown by Wiener that when coloring matter was injected into the circulation of the mother, the amniotic fluid was stained at the end of a few minutes, and the meconium was also soon colored by the swallowed fluid, while at the same time not a trace of coloring matter could be found in the kidneys or other organs of the fœtus We might also suppose that occasionally the amniotic fluid would be infected from the interior of the uterus itself, as the lymphatics of the amnion have been shown to be connected directly with those of the uterus Escherich has examined bacteriologically the meconium of three infants that died during birth Within a few hours after the birth of the fœtuses, their abdomens were opened under every indicated precaution, and double ligatures put about one or more loops of intestines These were then washed with a sublimate solution, and opened with a sterilized knife From the contents of these loops, inoculations were made in peptonized beef tea gelatin, and in liquid sterilized blood serum After incubation for several weeks, no change was discernible, so that in these three cases at least, the intestinal contents were free from any micro organism that would grow in the mediums used The same experimenter found the meconium of infants that lived only a few hours infected by very few kinds of bacteria, and these in small numbers, but if the child lived a day or more, the individuals, as well as the species, became quite numerous There is no doubt, therefore, that it furnishes abundant nutrition Breslau has shown that the presence of swallowed air in the intestines of newly born infants can be demonstrated very early by means of percussion Escherich considers that the meconium is infected by germs swallowed with the air and dust, in the first efforts of sucking

The examination of the meconium chemically, while less reliable than the preceding method, furnishes a valuable confirmation Search was made by Forster, Zweizel and Muller in the meconium of still born, for products of putrefaction such as indol and phenol, with negative results

Thus by three separate methods the fœtus has been shown to be free from all micro organisms, and, therefore, when retained in the body of the healthy mother after its physiological or pathological death, is incapable of giving rise to suppuration or destructive inflammatory disturbances

5 It frequently happens in twin pregnancies within the uterus that the death of one of the fœtuses results after it has attained a considerable size In these cases the dead fœtus and its annexa seldom give rise to suppuration or inflammation, or hasten in any manner the delivery of the still living infant At times, also, fœtuses at full term are retained a long time within the uterus, through one cause or another, without producing any unfavorable result

Bandl cites thirty cases of pregnancy in a rudimentary horn of the uterus, seven of which were retained six months or longer, and in no case did suppuration ensue It would doubtless be difficult to diagnose a tubal pregnancy from one in a rudimentary horn, even on the cadaver, after any considerable suppuration This may account for the limited number of observations of this occurrence

Since infection of a dead fœtus in the uterus or in a rudimentary horn is such a rare occurrence, the infection of a fœtus outside this organ and far removed from infection from the interior of the uterus, the cervix, or the vagina, one would expect to be much more rare

Unfortunately, this *a priori* conclusion does not seem to be verified by experience Kiwisch collected 100 cases of extra uterine pregnancy of all kinds, and it appears from the summary of his cases as given by Bandl that about 37 per cent of these fœtuses became infected

Seventeen died of peritonitis more or less acute, 4 died of peritonitis after the fœtus had been long retained, 9 died through a long continued suppuration and perforation, 7 recovered after spontaneous elimination Hecker collected 132 cases, out of which it seems that about 47 per cent became infected, 18 died of hectic, 12 died of peritonitis, 28 recovered after discharge of the fœtus through the rectum, 15 recovered after discharge of the fœtus through the abdominal wall

Out of 500 cases of extra uterine pregnancy collected by Parry, 248 went to or beyond the full term, and, out of this number, seventy fœtuses were discharged either through the rectum, the vagina, or the abdominal wall The history of most of these cases shows that this issue was brought about by suppuration, and consequently through infection Thus, in Parry's cases, 28 per cent can be considered as infected During the first year, 12 per cent of the whole number terminated in suppuration, during the second year, 5 per cent, during the third year 2½ per cent After this time, less than 2 per cent were infected each year

The examination of the statistics from all these sources would lead one to think that there are some sources of infection of dead extra uterine fœtuses which are not present in cases of cerebral hæmorrhages, pelvic hæmorrhage, hæmorrhage into the large joints, or about simple fractures In these cases absorption is the rule, and infection and consequent suppuration rarely take place

6 The three possible methods of infection which seem to be worthy of consideration are the following 1 Infection of the fœtus before its death, and subsequent suppuration 2 Simple auto infection, so called 3 Infection through the proximity of pyogenic bacteria or their spores left behind from some previous suppuration

The first of these methods seems hardly worthy of consideration The difficulty of the passage of the microbe from the infected blood of the mother is clearly shown by the experiments of Bollanger He injected into the blood of pregnant sheep the living anthrax bacilli After a sufficient time had been allowed for the disease to show itself, the animal was killed The fœtus was then removed, and found perfectly free from bacteria Klotz found in the whole literature only six cases in which the fœtus was infected with measles during intra uterine life

A simple auto infection certainly cannot account for such a large per cent of infection of extra-uterine fœtuses, since we have seen that this is such a rare occurrence within the uterus itself and in the rudimentary horn It has been impossible for me to find any statistics relative to the frequency of infection of hæmorrhagic products in different parts of the body I can only appeal to the experience of every surgeon to testify for me that it is extremely rare The consideration of Parry's cases in which a large per cent became infected during the first year, with a gradually diminishing percentage afterwards, is, in itself, quite significant, and shows plainly that whatever the source of infection is, time alone is a very insignificant element

I now pass to the third possible source of infection Leitzman considers the contiguity of septic germs as a possible source of infection in these cases, and Spiegelberg declares that lithopœdia may excite suppuration, and that the frequency of this issue is encouraged by labor There seems to be one factor which Bandl admits to be largely concerned in the etiology of extra uterine pregnancies which has not received consideration I refer to the presence of residues of old inflammations in close proximity to the dead fœtus There is every reason to believe from the consideration of Martin's researches and compilation that these residues which result in the occlusion of the tubes and consequent pathological fetation, are the result of septic or infected inflammation, and it is probable, although, as I have said, yet unproven, that these residues, in a large majority of cases, contain lasting spores By pressure atrophy from the weight of the dead fœtus, these are brought into connection with a large and rich pabulum, in which they germinate and multiply, and from which they infect the surrounding living tissues In these they give rise to suppuration, which infiltrates the connective tissue in the direction of the least resistance, and subsequently spontaneous elimination of the fœtus may take place There seems to be but one thing to be proven to render my consideration of this most potent cause probable It remains to be shown that spore formation in pyogenic bacteria does take place within the living human body, and that these spores are left behind in the cicatricial tissue resulting from suppurating granulation

7 If further investigation and research should prove the presence of lasting spores in previously infected tissues and the possibility of their causing subsequent suppuration, their presence should be considered when operating for the removal of living or dead extra uterine fœtuses, or for diseased tubes In case any doubt of the sterility of such a fœtus or its surroundings should exist, the fear of the presence of lasting spores would be an additional indication for the use of the antiseptic drain, and the treatment of the sac as an abscess cavity

It would also render the prognosis less favorable in cases where it is deemed advisable to produce death artificially, early in the life of such an extra uterine fœtus Especially should caution be exercised in case of puncture, as this means might make a way, and, at the same time, furnish a material for the latent spores about

PHILADELPHIA COUNTY MEDICAL SOCIETY

Stated Meeting, September 28, 1887

THE PRESIDENT, J SOLIS-COHEN, M D, IN THE CHAIR

DR A C W BEECHER reported a case of

COMPOUND FRACTURE OF THE HUMERUS AND INFERIOR MAXILLA, AND OTHER INJURIES, FROM A FALL

F L, female, æt 4 years On May 20, 1885, fell

from the third story front window of her home into an area leading into the basement, a distance of 38 feet, in her descent she probably struck an iron railing on the steps (which were winding) leading to the front door, which railing was somewhat movable from side to side, having become loosened at one end As no one saw her falling, it is not known precisely how she struck She was immediately removed to a hospital, where her wounds were dressed, and in two days her mother removed her to her home, and Dr G W Sparks, the family physician, was sent for, with whom I was subsequently associated in the treatment of the case On May 24 I saw her for the first time with Dr Sparks, and as she seemed quite comfortable, and the dressings in place, we did not remove them, but on a subsequent visit, not knowing the character or extent of the injuries, and the discharges being profuse and offensive, the dressings were removed, and then we found a deep, lacerated wound on the thoracic side of the right axilla, about 4 inches in length, extending from in front of the margin of the tendon of the pectoralis major muscle, backward to behind the tendon of the latissimus dorsi, and both of these tendons were somewhat torn (the wound had been brought together by several interrupted sutures when dressed at the hospital, but these had cut out and I did not replace them) No fracture of the ribs, but a fracture of the humerus, probably an epiphyseal separation of the head of the bone from the shaft, as it seemed to be in that situation A contusion on the posterior surface of the shoulder, over the head of the bone, developed a slough and abscess, which was drained by a seton into the wound in the axilla, so as to prevent the burrowing of pus The arm was left to hang in a line corresponding with the long axis of the body, and the lower part of the arm and forearm were firmly strapped to the chest by adhesive strips, absorbent cotton and iodoform were placed in the armpit and over the shoulder, and bandages applied over the strips in such a manner as to leave the shoulder bare and the armpit accessible, a felt shoulder splint, well padded, was then applied to fix the shoulder, and a bandage over the whole The outer bandage and the splint had to be removed about once in two days to permit the treatment of the wounds underneath, they were washed out by injecting a solution of carbolic acid The under bandages were only removed when they became displaced or were too much soiled

A small bruise was noticed on the right side over the crest of the ilium, this gradually degenerated into an abscess containing about an ounce of pus An examination did not discover any dead bone, a drainage tube and carbolized cotton were applied, and in due time the abscess healed very kindly

About three weeks after the injury my attention was called to a small tender spot and swelling on the under side of the lower jaw, to the left of the symphysis An examination showed that some teeth in the lower jaw near this point had been broken off in the fall, and that one or two loose fragments remained, which I removed with dressing forceps There was no evidence of complete fracture of the jaw, no displacement, and no crepitation, yet an abscess developed, which was opened externally Ether was administered for the better examination of the jaw, and a communication was found to extend from the external wound through the jaw into the mouth, and that there were evidences of dead bone, several fragments of which, and two permanent teeth not evolved, were removed, after which it healed up rapidly Special directions that only liquid food should be administered, so as not to complete what certainly was a partial fracture of the jaw, which the act of chewing would have tended to bring about

The shock in this case was quite severe and an irritative fever set in, the discharge of pus was profuse, the appetite was capricious and poor, all of which produced rapid emaciation, and her life was threatened A liberal administration of quinia sulph in syr glyc c, whiskey, dessertspoonful every three hours, milk, eggs, and beef tea, rigidly insisted upon, she soon rallied The wound under the arm gradually closed, leaving a neat cicatrix, and about July 1 slight passive motion was instituted, which showed that there was little stiffness in the joint, that the cicatrix held to a slight extent the tendons of the pectoralis major and latissimus dorsi muscles, restraining their action somewhat, there was also a lack of power in some of the other muscles of the chest, either for want of use or because they had been injured in the fall

In the latter part of July the child was taken to camp meeting, tripping over a board, she was thrown upon her injured shoulder against a large stone She was brought home, and an examination revealed crepitation at the point of original separation The arm was again bandaged to the body, the splint applied to the shoulder, and a recovery soon followed She had had several other falls before and after the above mentioned, but with no bad results to the injured member

We have supposed that in the descent from the window the arm was extended from the body in the endeavor to save herself, that her body struck the railing, producing the laceration, with the arm on one side of the railing and the body on the other, that the body was turned by the resistance, the leverage throwing the force against the humerus near its head, and the leverage of the arm and forearm produced the separation of the head from the shaft The mobility of the railing, together with its angle of inclination, doubtless broke the force of the direct fall from the window, materially reducing it by the time she reached the area, and probably saved her from instantaneous death How and when in the descent the other injuries were produced is mere conjecture, probably on the steps in the area

It seems almost providential that she was not instantly killed, and that she did not perish from shock and septicæmia, the large vessels and nerves of the axilla just escaped most serious injury, which will account for the saving of the arm from gangrene or amputation, or both

She has recovered, with great mobility of the arm at the shoulder joint, which will be further increased as the products of inflammation become absorbed, and from use of the limb

DR O H ALLIS said I think that inasmuch as this was a compound fracture, it would have been good surgery to remove the detached epiphysis The fact, however, that good union and good motion were obtained, seems to show that this would have been an error It is also stated by authors that, where separation of the upper humeral epiphysis occurs, this portion of the bone undergoes necrosis, its blood supply not being sufficient to support it The result of Dr Beecher's case would seem to indicate that this also was incorrect

DR BEECHER said I am not prepared to say positively that this was a case of epiphyseal fracture or separation, though I believe it was—the injury was so high up I should like to ask if any observations have been made with reference to the growth of the bone subsequent to epiphyseal separation?

DR H R WHARTON said I had a case at the Children's Hospital some time ago of a compound fracture high up in the humerus The upper end of the lower fragment projected into the axilla a distance of two inches An inch and a half of the lower fragment and a spiculated fragment attached to the head of the bone were removed The fracture was then reduced and dressed antiseptically and the case did perfectly well In four weeks there was perfect union and perfect motion In this case the question came up whether or not there would be sufficient nutrition to keep up the vitality of the head of the bone It was decided to make the attempt to get union, for if necrosis occurred it would be a simple matter to remove the head of the bone In connection with Dr Beecher's question, I can say that in severe cases of epiphyseal fracture which I have had under observation for several years, I can detect no difference in the length of the humeri of the two sides

(*To be concluded*)

LA SALLE COUNTY (ILL) MEDICAL SOCIETY

Meeting of May 10, 1887

DR J O HARRIS, of Ottawa, Ill, read a paper on

THE PRODUCTION AND USES OF MOIST HEAT IN THE TREATMENT OF DISEASE, OR AN EFFICIENT MEANS OF PRODUCING SPEEDY DIAPHORESIS

He described his method of developing moist heat, and illustrated its practical application substantially as follows Get a tinner to make a round tin box, eight inches in diameter and four inches deep, have him attach an open handle or socket three inches long and one and a quarter inches in diameter on one side near the top, attach a hinged cover perforated with one half or five eighth inch holes, bend at right angles two pieces of tin doubled, half inch in diameter, across the cover, then put a wooden handle fifteen inches long, in the socket, and your apparatus is ready Being called to a case presenting all the symptoms of a congestive or pernicious chill, he sends a messenger for a quantity of unslacked lime, and while waiting his return gives the patient ten grains of Dover's powder, and has some woolen sheets or blankets brought and his patient placed between them As soon as the lime is at hand he partly fills the tin box with it, pours over it a pint of hot water, closes down the cover, places the box between the patient's legs, and tucks the blankets down close around the patient In ten minutes he says the chill has disappeared and the patient is bathed in profuse perspiration In half an hour he allows the moist flannel sheets to be removed and replaced by dry warmed cotton ones, and directs the necessary antiperiodic remedies for preventing a recurrence of the chill Dr Harris further illustrates the efficiency of his method by the two following cases

Miss F F D had been out on a damp, chilly day while "unwell," with thin shoes, and her monthly flow was suddenly stopped, followed by terrible pains in the pelvis and loins The use of the tin sweat-box with lime in the manner previously described, speedily induced profuse general perspiration with relief of pain, and in a few hours the menstrual flow had returned

The other was N C, a merchant with an unusually severe attack of acute rheumatism, caused by a thorough wetting while out hunting and overtaken by a cold rain Being called the next evening, and finding the patient suffering intensely, he gave him at once a powder composed of pulv opii grs iss, nit pot grs x, and pulv zinziber grs ij, and went out for his sweat box and lime Returning he applied it between the legs of his patient under woolen coverings, in the same manner as previously described At first the patient was disposed to ridicule the remedy, but soon admitted that it was getting warm, a little later asked to have some of the heat "let out," and finally declared he was being "cooked alive" "The result of the operation was that in less than an hour my patient was free from pain, and by noon the next day was walking around the store"

FOREIGN CORRESPONDENCE

LETTER FROM LONDON

(FROM OUR OWN CORRESPONDENT)

St John Ambulance Association—Salicylate of Mercury—Salicylate of Lithia—Visceral Symptoms in Acute Rheumatism—Ether an Adjuvant to Strophanthus—Homœopathy in Liverpool—Loss of the Nails in Telegraph Operators

The work of the St John Ambulance Association has attained a magnitude that could hardly have been anticipated at the time of its commencement in 1877 The Annual Report of that organization shows that it has established administrative centers in all parts of the World Its object is to disseminate sound information as to the best means of affording first aid to the injured Ten years ago its benefi-cent proposals were received with very general reserve To be able to give trained and intelligent assistance in case of accident was obviously very desirable for everybody, but the practicability of rendering the generality of persons capable of doing

so seemed to many very doubtful The Association has now 270 administrative centers and considerably over 100,000 certificated pupils, all of whom have passed through a course of instruction fitting them to deal in a skilful and rational method with any of the ordinary accidents of life until professional aid can be procured Last year 15,751 "First Aid" certificates were granted, 8,869 having gone to men students, and 6,882 to women There is something perhaps slightly fantastic in this Association setting up classes in China to show the natives how to deal with a broken leg or a dislocated ankle until the doctor arrives One such class was last year established at Kaiping Mines, 80 miles from Tichtsin An ambulance corps was also established in connection with the Midland Railway's carriage works at Derby, and also classes were trained of Metropolitan Railway employès at Baker Street Station This organization is certainly proving immensely useful to the police in various parts of the Kingdom and the Metropolitan men appear to be taking to the training with very creditable zeal Its practical utility received signal illustration on the day of the Jubilee service when no fewer than from 500 to 600 casualties were treated

Two new salicylates have been recently introduced into therapeutics, salicylate of mercury and salicylate of lithia. Salicylate of lithia is insoluble, and the best method of obtaining it is to act upon the carbonate of lithia by salicylic acid as follows twenty grams of the carbonate suspended in distilled water, are placed in a porcelain dish, and the mixture slightly warmed, whilst the salicylic acid is gradually added as long as any carbonic acid is evolved This will take about eighty grams of commercial salicylic acid as pure as possible Consequently the lithia salt of salicylic acid, contains about three sixths of its weight of the latter When the evolution of carbonic acid gas has ceased, there is found an abundant and dense precipitate, this is washed with distilled water and dried It is recommended to use this salt at the dose of three grams every two hours, increasing or diminishing the dose according to the case

The salicylate of mercury is a greyish white color, insoluble in water, and up to the present has been found a good preparation for being made into ointments, one to twenty five of vaseline

Dr William Robinson has drawn attention to an interesting case of acute rheumatism under his care, in which the visceral affections eclipsed those of the joints It occurred in a young woman aged 17 years When first seen she was in bed with severe pain in abdomen, increased on pressure, pulse 110, temperature 99 4° F and all the symptoms of acute peritonitis There were no signs of pelvic or renal disease and normal menstruation had ceased five days before For the first week pain was kept under by opiates, the temperature rose to 103° and the breathing was altogether costal At the end of the week severe pain paralyzed the right knee, it became very tender but was neither red or swollen, the temperature rose to 104°, and signs of pericarditis developed After two days the left shoulder was attacked with acute pain, also without redness or swelling, the right knee at the same time becoming free In a few days the left elbow followed suit As the pericarditis developed, the abdominal symptoms gradually subsided but double pleurisy with effusion came on At the end of the second week the pericardial mischief greatly increased, the heart impulse being felt on a level with the nipple From this time up to the end of the fifth week gradual improvement took place, the abdominal tenderness, tympanites and increased heart dulness had almost gone and the temperature and pulse had become normal, when a relapse of peritonitis recurred and pain returned to her left shoulder, the patient again suddenly recovered, but was left with a systolic bruit Dr Robinson drew attention to the extreme rareness of peritonitis occurring in acute rheumatism, the affection being chiefly mentioned and described by French writers

Dr T Broadbent finds that the addition of ether to the dose of strophanthus of great use in cardiac affections When he first used strophanthus in cases of heart disease he was invariably unfortunate in his results until ether was used in combination, recently in a case of very bad double pneumonia, with heart failure he combined strophanthus with an expectorant, the case got rapidly worse, the respiration going up to 65, the pulse to 130 and the patient became cyanotic As a last resource strophanthus and ether only were given, the symptoms began to abate immediately and the patient made a rapid recovery

The new homœopathic hospital has been formally opened at Liverpool The erection of an institution to be devoted entirely to homœopathic treatment of disease was decided on three or four years ago by Mr Henry Tate, the well known sugar refiner It is at present intended to contain fifty beds, but capable of being enlarged to contain twenty or thirty more There are large male and female wards, convalescent rooms, two infectious wards, completely isolated from the rest of the building, separation wards and private wards, together with carefully arranged offices, medical officers' and nurses' rooms, etc The greatest possible attention has been paid to the drainage and the means of warming and ventilation. Ever since the first homœopathic dispensary was opened in 1841, Hahnemann's form of treatment has been growing more popular in Liverpool In 1867 a second dispensary was opened and in 1885 the in-door and out-door patients treated at these establishments numbered 78,881 or a weekly average of 1,516 The cost of the building has been £20,000 The day preceding the opening the twenty third annual conference of "homœopathic" practitioners was held in the building, and much stress was laid on the want of a first class "homœopathic" surgeon, and hopes were expressed that one would speedily arrive in Liverpool

A new ailment is stated to have shown itself among telegraph operators, namely the dropping off one after the other of the finger nails, two cases have recently occurred in otherwise healthy subjects, the curious affection is thought to be due to the constant jar caused by hammering and pushing with the finger ends in working the Morse system of telegraphy

DOMESTIC CORRESPONDENCE

CATHETERIZATION OF THE EUSTACHIAN TUBE

Dear Sir —In THE JOURNAL of October 15 there was published a letter from Dr Enfield concerning the faucial method of introducing the Eustachian catheter The doctor cauterized the Eustachian tube per fauces because the nasal septum was so deflected as to render the introduction of the catheter through the inferior meatus impracticable It did not seem to occur to him, and I have observed that it does not to many others, to catheterize through the opposite nostril, to the advantage of which the deflection has taken place This can be accomplished in the majority of cases, and obviates the necessity of introducing the catheter through the mouth and fauces Deflected septa and hypertrophied turbinated bodies are very common in adults, and often constrict the inferior meatus to such a degree as to make it very difficult to insert the catheter of ordinary calibre In such cases the smallest silver catheter, with the beak but slightly curved, may often be passed by engaging the point under the end of the inferior turbinated body, rotating the catheter upon its axis, elevating its proximal end and, at the same time, carrying the instrument backward toward the orifice of the Eustachian tube After placing the catheter in the initial position, if one allows it to direct its own course, as it were, when it meets with obstruction, it will generally find its way through, even if the spiral line pursued by the beak quite describes a circle There are cases in which the unyielding silver catheter cannot be introduced, where we may succeed with the small hard rubber catheter, the flexibility of which permits of its easy adaptation to considerable inequalities and curves in the inferior meatus

These facts are mentioned for the benefit of any cases that cannot be catheterized through the nostril opposite to the tube we wish to reach However, those cases must be rare in which it is impossible to pass a catheter through one or the other nostril, for, as common as deflection of the septum and hypertrophied turbinated bodies are, I do not recall a case in which it was not possible to catheterize through one meatus It should not be forgotten that a curve of the septum toward one nostril increases the capacity of the other, and with the amount of thickening of the septum which usually accompanies this deflection there is left ample room for the entrance of a small catheter Another important point must be observed In order to reach the Eustachian aperture through the nostril of the opposite side, the beaks of our catheters should be given a curve describing an arc of a greater circle than we find in them as they come from the instrument makers This curve should be sufficient only to reach the orifice of the opposite Eustachian tube, otherwise it will impede the passage of the catheter through the nostril

I have practiced this method for several years, and have found it appreciated by patients, inasmuch as it removes one half the discomfort of treatment and saves time The success attending this method may be easily demonstrated by means of the auscultating tube

That catheterization per nasum is more simple and more certain of success than per fauces, except in case of cleft palate, needs no elucidation Very truly yours, S S BISHOP, M D

719 W Adams St , Chicago

SUDDEN DEATH FROM HEART DISEASE

Dear Sir —On September 27 Dr J E Chandler, æt 27, of Rowley, Iowa, while in his office and in the act of placing upon the table a pair of tooth forceps with which the moment previous he had extracted a patient's tooth, fell instantly dead without uttering a word or sound Dr Chandler was a recent and specially competent young graduate in medicine, and a former student in the office of Dr G G Wilson, of this city

Some years ago the deceased suffered a severe rheumatic attack, although not arthritic in type For two or three years he has developed heart symptoms, including a mitral systolic murmur This condition was not of sufficient gravity to interfere with his business and was, in fact, unknown by most of his intimate friends Some four weeks previous to his death he was examined by the writer for a suspected organic liver trouble, the functions of the liver being impaired, with loss of appetite and nausea The liver was found normal, and with the use of usual treatment the symptoms rapidly abated and, aside from some remaining debility, the doctor had recovered his former and usual condition At the examination referred to he made no allusion to his heart, and nothing in his appearance, or symptoms with which he complained, then directed attention to it There was no autopsy

Will some one explain how a lesion of the heart so slight in its previous effects can produce instant death? H C MARKHAM, M D

Independence, Iowa

PLEASE WRITE PLAINLY

Dear Sir —Through the recent offer made in your advertising pages to send our complimentary sample of Platt's Chlorides to any physician still unacquainted with it, we have received many hundreds of requests, which we have complied with, with pleasure But there will be a few who will be disappointed by reason of their own carelessness or thoughtlessness in writing, it having been either impossible to decipher the name or the P O address, or the latter has not been fully given For instance, one physician gives his P O address as simply Harper's Ferry, not naming the State There being a Harper's Ferry in Iowa, one in Kentucky and another in West Virginia, it was impossible to tell where to send our sample, as, in this instance, the physician's name was not in any of our directories, and the post mark was entirely obliterated We will continue our offer to send samples (expressage prepaid by ourselves) for a

few weeks yet, and would kindly ask those requesting same, to enclose their card, or to write on a letter head giving the name and address in print

Most respectfully,

HENRY B PLATT

36 Platt St , New York

NECROLOGY

DAVID RICE M D

DAVID RICE, M D , of Leverett, Mass , was born of humble but highly respectable parentage in the town of Rowe, Mass , July 25, 1819, and died at Leverett, Mass , of dropsy of the heart, August 29, 1878 His boyhood was spent at his native place He was always hard working, boy as well as man He taught school one or two terms in Rome When about eighteen he left his home and went to Berkshire Medical College, Pittsfield, Mass , where he graduated with high honors in 1842 Thence he went to Leverett and entered into partnership with the late Butler Wilmarth, M D , who was a victim of the terrible Norwalk disaster in 1853 Dr Wilmarth and Dr Rice were like brothers all their lives, and were in partnership for many years, when finally Dr Wilmarth became a homœopathist and settled in Hopedale, and Dr Rice remained in L , where he practiced medicine for forty years He stood foremost in his profession, and was beloved by all his medical brethren, who looked upon him as a physician of sound judgment and high integrity

He was, very early in his professional life, a member of the Massachusetts Medical Society He wrote many articles for the medical journals, one of which was copied into the London *Lancet*, referring to an instrument of his own invention, for extracting fish bones from the throat

In July, 1844, he married Miss Harriet Clapp, of Chesterfield, who was a graduate of Mt Holyoke Seminary in 1842 Mrs Rice was a lady of high culture and proved herself a loving helpmate for forty years of wedded life In the latter years of her life she was associated with her husband in the practice of medicine, and had a most successful practice before and after his death, until her decease in 1885

Dr Rice was an associate member with Butler and Sumner in the House of Representatives in 1853, both were very warm friends of his, as after years proved by the many mementoes sent him by them He became a member of the American Medical Association in 1865

The Doctor was a loving husband and tender father, as well as a kind and charitable neighbor and citizen, and honest in all his dealings Always a sunbeam in the sick room, and when his tired spirit took flight to the mansions of rest, it was on every one's lips, "*How can we* spare him?" He was always untiring in his efforts to save life He was a Christian man and a very prominent member of the Congregational church for many long years, always ready to do his part, and for many years a member of the choir He was influential as well as public spirited, and was for many years chairman of the school committee He was buried with Masonic ceremonies, being a member of that order J F W

JEFFERSON PRATT, M D

Jefferson Pratt, M D , of Hopkinton Mass , was born in Belchertown, Mass , June 6, 1803, the youngest of a family of sixteen children His father was a captain in the Revolutionary Army He was a graduate of Berkshire Medical College, Mass , and commenced the practice of medicine and surgery in Hopkinton in 1827 In 1829 he married Miss Harriet Valentine Harrington, of Hopkinton, who with two daughters survive him He was a member of the Massachusetts Medical and other societies, was a man of strong individuality, and comprehensive in his diagnosis and treatment of disease He was a member of the American Medical Association from 1856, and attended meetings in 1858, 1864, 1865, 1868 and 1870

After a successful practice of more than fifty years, he died suddenly at the residence of his daughter, Mrs J C Whitin, of Hopkinton, in 1883, having just returned from a family picnic

BOOK REVIEWS

THE PRINCIPLES OF ANTISEPTIC METHODS APPLIED TO OBSTETRIC PRACTICE By DR PAUL BAR, Accoucheur to, formerly Interne in, the Maternity Hospital, Paris, etc Translated by HENRY D FRY, M D , 8vo, pp vii–175 Philadelphia P Blakiston, Son & Co 1887 Chicago W T Keener

Those who have some doubts as to the value of antisepsis in obstetrics should read Dr Bar's book and have them removed Those who have no faith at all in antiseptic obstetrics should read it, if they are still open to conviction, for the purpose of seeing if they may not be mistaken in their views Those who thoroughly believe in practicing obstetrics on antiseptic principles should read the book in order to be doubly assured that they are right in their practice For while the reader will soon discover that the author is an enthusiastic believer in the use of antiseptics in obstetrics, he will see at the same time that Dr Bar is a conservative enthusiast, he never lets his enthusiasm carry him beyond the point of being guided by precise indications alone in his practice and teachings Nor will any one wonder at his enthusiasm after reading the third chapter, on "Influence of Antiseptics on Puerperal Epidemics"

Probably most physicians in this country have become somewhat familiar with the subjects of the greater number of chapters in Dr Bar's book But nevertheless, the author presents his material in a pleasing manner, and often in a new light, and no one, after reading the book, can claim that it is dull

or that he has wasted his time The first chapter on the "Relation of the Germ Theory to the Puerperium," and a part of the second chapter, on "The Antiseptic Method and Agents," are the key to the whole subject, and we think that some readers, at least, will find in them much that they have given no attention to before

Considering its small size the book contains a very great deal The subjects of the first three chapters have been mentioned The other chapters deal with Disinfection as an Antiseptic Measure, Hygiene of the Puerperium, Antisepsis during Labor, Antisepsis during the Third Stage of Labor, Antisepsis during the Puerperium, Antisepsis in Catheterization, The Antiseptic Method in Rupture of the Uterus, The Antiseptic Method in the Cæsarean Operation, and an appendix on "Antisepsis to the Umbilicus," and "Ophthalmia Neonatorum" Every physician who does obstetric work should study this book

PULMONARY CONSUMPTION Its Etiology, Pathology and Treatment, with an Analysis of 1000 Cases to Exemplify its Duration and Modes of Arrest By C J B WILLIAMS, M D, LL D, F R S, etc, and CHAS F WILLIAMS, M A, M D, etc Second Edition, enlarged and rewritten by Dr C F Williams 8vo, pp 446 With four colored plates and ten wood cuts Philadelphia P Blakiston, Son & Co, 1887 Chicago W T Keener

The first edition has made this work known to the profession We can not here describe it with the detail that it deserves The chapters on pathology are interesting and accurate These are well illustrated The colored cuts are admirable, showing the appearance and distribution of tubercle bacilli—the tissues In connection with the characteristic lesion of tubercular phthisis are described the various secondary changes brought about in the lungs and thorax generally, such as displacement of organs, modification of the shape of the chest, etc The chapter devoted to the "Predisposing Causes of Consumption" is also most interesting and instructive The subject of treatment is considered in chapters, with the following headings "Prophylactic and Anti-Phthisical," "Climatic Treatment of Consumption," "Antipyrexial," "Palliative Treatment of Consumption," and "Antiseptic or Bacillicide Treatment" The last chapter, while it covers completely the ground of antiseptic treatment of phthisis, does not furnish us much hope of successfully combatting the disease in this way Without doubt the prophylactic treatment remains the most important

MISCELLANEOUS.

HEALTH IN MICHIGAN —For the month of October, 1887, compared with the preceding months, the reports indicate that bronchitis, pneumonia, remittent fever, scarlet fever, diphtheria, and tonsilitis increased, and that diarrhœa, dysentery, cholera morbus, cholera infantum, and typhoid fever decreased in prevalence Compared with the preceding month, the temperature in the month of October, 1887, was considerably lower, the absolute humidity was much less, the relative humidity was less, the day and the night ozone were more Compared with the average for the month of October in the nine years, 1879-1887, intermittent fever, consumption of lungs, diphtheria and diarrhœa were less prevalent in October, 1887

For the month of October, 1887, compared with the average of corresponding months for the nine years, 1879-1887, the temperature was considerably lower, the absolute humidity was less, the relative humidity was the same, the day ozone was slightly more, the night ozone was less Including reports by regular observers and others, diphtheria was reported present in Michigan in the month of October, 1887, at fifty eight places, scarlet fever at thirty six places, typhoid fever at forty five places, measles at twelve places, and small pox at one place. Reports from all sources show diphtheria reported at seven places more, scarlet fever at five places more, typhoid fever at one place less, measles at seven places more, and small pox at the same number of places in the month of October, 1886, as in the preceding month.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM OCTOBER 29, 1887, TO NOVEMBER 4 1887

Capt Paul R Brown, Asst Surgeon, leave of absence extended one month S O 250, A G O, October 27, 1887

Capt Chas B Byrne, Asst Surgeon, ordered for temporary duty at Ft McHenry, Md S O 231, Div Atlantic, October 28, 1887

Capt Curtis E Munn, Asst Surgeon, relieved from duty at Ft Canby, Wash Ter, and ordered for duty as Post Surgeon at Ft Klamath, Oregon S O 251, A G O, October 28, 1887

Capt G W Adair, Asst Surgeon, the leave of absence for seven days granted on the 27th inst by the commanding officer, Ft Brady, Mich, is extended twenty three days. S O 231, Div Atlantic, October 28, 1887

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY, DURING THE WEEK ENDING NOVEMBER 5 1887

Surgeon P Fitzsimmons, ordered to the U S S "Marion."

Asst Surgeon L W Atlee, ordered to the U S S "Marion"

Medical Inspector N L Bates, ordered to the U S S "Trenton"

P A Surgeon Henry G Beyer, ordered to the U S S "Trenton"

Asst Surgeon Stephen S White, ordered to the U S S "Trenton"

P A Surgeon P M Rixey, detached from the U S S "Trenton" and wait orders

P A Surgeon Richard Ashbridge, ordered to the U S S receiving ship "St Louis"

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE WEEK ENDING NOVEMBER 5, 1887

Surgeon C S D Hessenden, detailed as chairman of Board for the physical examination of officers of the Revenue Marine Service November 1, 1887

P A Surgeon F W Mead, detailed as recorder of Board for the physical examination of officers of the Revenue Marine Service November 1, 1887

P A Surgeon A D Bevan, relieved from duty at Portland, Oregon, ordered to Marine Hospital, New York November 2, 1887

P A Surgeon P M Carrington relieved from duty on Revenue Str "Rush," ordered to Marine Hospital, San Francisco, Cal November 2, 1887

Asst Surgeon T B Perry, relieved from duty at Marine Hospital, San Francisco, Cal, ordered to assume charge of Service at Portland, Oregon November 2, 1887

Asst Surgeon H T Goodwin, relieved from duty at Norfolk, Va, ordered to Marine Hospital, New Orleans, La November 5, 1887

PATHOLOGICAL HEREDITY AND CONGENITAL ABNORMALITIES OF THE TEETH

Read before Section on Dental and Oral Surgery, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY ALTON H THOMPSON, D D S,

OF TOPEKA KANSAS

Heredity is that force by which every organism, plant or animal is formed in the likeness of, and is the counterpart, more or less exact, of the parent forms which produced it Its external form and features, its internal organs and tissues, are copied after the type of the species to which the organs belong, and all its distinguishing peculiarities are characteristic of that species There is a law of type which governs the evolution of every molecule, the placing of that molecule in the building of tissues, the arrangement of those tissues in the growth and position of organs in the construction of the individual, so that it shall be a typical, representative organism That law is heredity

It is not in the field of the normal physiological operations of this law, that we wish to study it at this time, but rather to inquire briefly into its workings when influenced by abnormal conditions, its pathology, and that as especially manifested by abnormal development of the teeth and their environments There has long been a conviction in the minds of the scientific men of the profession, that causes of defective tissual formation of the teeth must be sought for farther back than the life history of the individual, and that in the pre natal influences governing tissual character and quality, will yet be discovered many of the forces dictating those variations from normality in dental evolution which are so interesting, but too often most disastrous in their effects upon the arrangement and quality of the teeth

Like all other organs and tissues, the development of the physical peculiarities of the teeth is under the control of omnipresent hereditary influences, immediate and remote In no class of organs is the effect of inheritance by variation due to changed conditions so marked as in the teeth of man For instance, being peculiarly susceptible to the effects of use and disuse, they have, by the protracted influence of disease weighing upon and retarding their proper development for generations, become so defective and incomplete as to approach the condition of rudimentary organs in man, to a considerable degree The third molar or wisdom tooth, especially, is altogether rudimentary and is hastening towards extinction It is always defective, owing to deficient structural integrity, is often a dwarfed rudiment in size, and is frequently absent altogether, from mere failure to erupt, or perhaps to develop at all in the jaw

In man, transmitted variations are now under the domination of that artificial life with which he has surrounded himself He is far removed from a state of nature in the environments of civilization, and as a result the variations at present in progress in the species are rather detrimental than beneficial to his physical perfection and normal integrity of structure This is especially noticeable in the tendency to transmit imperfections and disease, so conspicuously manifested in civilized man to day And through the laws of and the persistence of disease and defectiveness, the teeth are the unfortunate recipients of a legacy of imperfections in varied forms In many other tissues and organs there is a tendency to spontaneous cure by gradual elimination during transmission, but with the teeth the opposite rule obtains, for diseases of these organs seem to be augmented by transmission Diseased malformations and defectiveness are rarely eliminated, even by the curative influence of a favorable crossing One reason for this perpetuation of disease seems to be that, owing to the depressing effects of disease, the force of heredity is directed towards the suppression of the teeth in accordance with the law of economy of growth, and the supplemental assistance of disease is allowed in the work of destruction Not only is the type of a tooth usually determined by the impress of one or another of the parents, but the particular defects and deformities are the result of parental impression or of unfortunate temperamental or consanguineous combinations Immediate effects are not always of most importance, although these are often paramount to the impressions of more remote inheritance Special defects are usually traceable to recently inherited imperfections, for, as Carpenter says, "the influence of parents on the constitution of offspring is strikingly manifested not merely in the mixture of their normal characters, but also in the tendency to hereditary transmission of perverted modes of functional activity which have been habitual in either parent Many diseases are accounted as hereditary, and perhaps others might be added to the list The predisposition may have been congenital on the part of the

parents or may have been acquired by themselves

The intensification that almost any kind of perversion of nutrition derives from being common to both parents, is most markedly evinced by the lamentable results which too frequently accrue from the marriage of individuals nearly related to each other and partaking of the same 'taint'" Or, aside from taint, even strong idiosyncrasy is frequently present which, by being intensified, may give rise to unfortunate physical or mental defects As evidence of the correctness of these observations on varied inheritance, we have the effects of syphilis, gout, phthisis, insanity, alcoholism, etc Regarding the effects of hereditary and transmitted disease upon the teeth, Dr Norman W Kingsley is an authority, and he says "Many of the common forms of irregularity are directly traceable to inheritance and are transmitted peculiarities Especially when it is confined to one or two teeth, the primary cause, so far as that individual is concerned, is an hereditary family peculiarity The teeth of every person possess more or less individuality, and most of the peculiarities which stamp them are inherited The form and color of the teeth, when not disturbed by abnormal influences, are derived from the same source Any departure from typal form is a peculiarity of descent as well as predisposition to defect or deformity It is a most wonderful subject for contemplation that, at some remote period in the history of our progenitors, nature departed from the normal type and produced a dwarfed lateral incisor or a twisted canine, or suppressed a bicuspid or a wisdom tooth, and following down the line of descent we find precisely the same peculiarity appearing and reappearing, perhaps not in the same line, but in the same family" As corroborating these observations, we notice that children frequently have the same defects upon the same teeth that the parents had, and that they become carious and are lost at the same age, or, owing to the increased ratio of defectiveness by inheritance so apparent in the teeth, are lost earlier in the child A mild defect of shape or contour, an extra cusp, a lingual fold upon the anterior teeth, total suppression of a tooth (as of a lateral incisor), the occurrence of caries in the same location, dark and imperfectly calcified spots similarly located in parent and child—all these and other defects and abnormalities of the teeth are often traced through families

The workings of the law of atavism often produce good results by causing the reappearance of a good denture in a family in which the teeth have long been imperfect and defective, with a prospect of its transmission and the elevation of the family type But, on the other hand, atavism also allows of the reappearance of a denture comparatively bad in a family which has good teeth, and with the danger of perpetuation Sometimes there is a blending of the types of two or more ancestors in the same individual—the front teeth representing a good organization of one parent and the back teeth the strumous, phthisical, etc , of the other, or *vice versa* These combinations vary infinitely and are apparently due to conflict of tendencies and the compromise of opposing elements Sexual limitations are also met with in all forms of hereditary diseases, and are more strongly pronounced in those diseases affecting hereditarily the skin and its appendages Thus abnormal deficiency or excess of the hair is apt to be accompanied by deficiency of the teeth and to follow in one sex. Peculiar malformations, malpositions and absence of the teeth often occur in the male line—perhaps more often than in the female Sometimes hereditary caries is limited to one sex in a very decided manner But in immediate descent the inheritance of form, color, quality and defectiveness of the teeth, is far more likely to be in reverse order as to the sexes

The son most frequently inherits the dental, as well as the other physical peculiarities of the mother, or failing here, through avatism he receives those of her father or of *his* mother The daughter, on the other hand, presents most frequently the characteristics of her father or of his maternal ancestors This is the law of reversal by sexes, and is largely prevalent in all transmissible peculiarities, abnormal as well as normal It is often observed in the transmission of disease from mother to son, or from father to daughter, the child of the same sex as the diseased parent escaping infection

Pathological heredity in relation to the teeth refers to disturbances of function which eventuate in defective dental development from causes received from parental impress The study of the pathology of dental embryology is now largely concerned with the investigation of the effects of transmissible diseases which directly affect the growing tooth germs, and their deleterious influence is now a well recognized fact Some observers claim that defective enamel is caused by acid fluids acting upon it during eruption, but the evidence is yet upon the side of the congenital and follicular effects of disease As Magitot says, "if the alteration were chemical in its nature, there would be no change in the centre of the organ, but this is always present Congenital lesions of the teeth, fissures, erosions, etc , are exclusively due to disturbances of dentinification and belong to the history of the follicular evolution"

When we contemplate the whole field of pathological heredity, of disease and predisposition to disease transmitted, of all kinds of debility and enervation so prevalent and transmissible, we cannot wonder that the teeth are so often defective, but rather that they are ever normal in any respect Most diseases affect the tooth germs, or other tissues and organs, in a particular way, so that peculiar markings are produced which are more or less characteristic and pathognomonic Some of these markings, as those of syphilis notably, have a positive diagnostic value to the pathologist Hereditary diseases inducing functional perversion cause abnormal constitutional conditions called *diathesis* or *cachexia*, and which are graded in intensity from a mere "taint" down to a state which is positively pathological and diseased

Persons inheriting constitutional taint, vitiated by diseased nutrition, have the entire system impressed in formation and saturated in life, by the toxical element of the disease This element degrades and deforms the development of tissues and organs, per

verts the physiological activities during life, and depresses the creative powers The fœtus which inherits such an influence is under the domination of a vicious power which retards perfect evolution, and with a special tendency oft times to the injury of special tissues or special classes of organs and tissues The developing teeth being so sensitive to all kinds of disturbing influences—for hereditary diseases affect primarily the skin and its appendages and related tissues—are most readily affected by the controlling vice Markings are often left as a permanent legacy of the disease which, as in the case of syphilis and gout at least, are of pathognomonic value Other diseases, as phthisis, scrofula, struma, etc, leave markings which have a less positive value, for their features are not yet certainly identified, and there are many others which may affect the teeth during development, of which we know little, but suspect much

The "Prince of Diseases," syphilis, holds a first place as a prime cause of disturbances of dental evolution The destructive and lasting impressions it leaves upon the teeth in embryo are unparalleled in pathological history, for when it affects the tooth germs severely, it produces teeth of hopeless deformity Much discussion has been indulged in by authorities as to its various signs, which are too familiar to be recapitulated here We need only call attention to the fearful effects of this great lesion as illustrating the disturbing influence of hereditary disease Gout, scrofula, struma, phthisis, etc, also produce teeth more or less characteristic as furnishing evidence of this power When these and kindred diseases and their resultant cachexia are thoroughly investigated, perhaps positive signs can be tabulated as accompanying each of them, but our knowledge is yet insufficient Suffice it that they do disturb formation and produce defective teeth, as do also many of the acute maladies of infancy

An interesting branch of this subject is the study of the effects of *racial* crossing, miscegenation, upon the arrangement and structure of the teeth We know that persistence of the peculiarities of race is one of the wonders of heredity, and that by its powers the permanence of racial characteristics is rendered possible Races of men exist to day whose ethnic features have remained unchanged through centuries, and will remain, because comparative purity of race has been maintained If racial persistence is so strong, it is not strange that mixture of races, and the conflict of various and often conflicting and heterogeneous qualities and incompatible tendencies of structure, should eventuate in imperfect, malformed and deteriorated organization We find this to be the case as regards the teeth in the unfortunate combination of large teeth with small jaws, first described by Dr J H McQuillen, and that this is a prime cause of irregularities of various kinds

Dr Kingslev, in describing this familiar fact, says that "aside from disease and imperfect development, most of the abnormalities of arrangement we see are to be charged to the crossing of races, especially as found in America among our Anglo Saxon population The persistence of race, the reappearance of external racial qualities erratically in all possible and unfortunate combinations, all contribute towards the degradation of the teeth and their environments" Mixing races always produces a deterioration of physical perfection, as a first result of crossing, and this, of course, is a prime cause of degeneracy of dental structure as well M Magitot has dwelt at length on this subject in his studies of dental caries He says that "in certain families and races caries is a frequent and habitual malady, through the transmission of certain anatomic predispositions of structure Thus certain predispositions of dentition, as anomalies of structure, reproduce themselves through successive generations" He found that among the mixed races in France there was more disposition to caries than among the comparatively pure races From the records of the War Department he constructed a map showing the geographic distribution of caries in France, which bore an exact relation to the ethnography of the nation, *i e*, the districts of the least prevalence of caries had pure races, and those having the most caries were in the belt of foreign invasions and consequent mixture of stocks

After the first effect of crossing, *i e*, physical degeneracy and depressed vitality, the most important result is the confusion of typal characteristics as a cause of deformity and deterioration, consequent upon the unsuccessful efforts of nature to harmonize discordant and conflicting typal elements It is a rule that inharmony of racial characteristics is an active cause of abnormalities of all kinds, and it follows that if pure races have the best physical development, they must have the best teeth, and which we find to be the case as a rule But the subject is too vast to venture more than these mere suggestions We are but upon the threshold of the subject of heredity, and especially in regard to the influence of hereditary causes as inducing imperfect dental development As Mr Chas S Tomes has recently said, "an enticing field of inquiry lies in the question of how far heredity plays a part in the genesis of dental irregularities and of dental caries As vast a number seems quite as likely to be under the sway of distinct heredity, as is the conformation of the nose or the lips Many families have peculiarities—a V shaped palate, marked charcteristics and abnormalities of the teeth, etc, running through all the members Close observation of the mouths of the children of large families in conjunction with the parents, might throw some light on the vastly wider question of heredity

"The question of how far the child is demonstrably a mere product, showing not only the peculiarities of the parents, but bringing to light again tendencies inherited from more remote ancestors, is one of the greatest interest, for in every individual many strains of blood unite and may be expected to exert themselves, to varying extents"

As Darwin has said, "the whole subject of inheritance is most wonderful," and we may add that the wonders it presents in normal action are only surpassed by the manifestations of its power in pathological condition, for the transmission of disease is more incomprehensible than the transmission of normal structure and qualities

CONGENITAL PHIMOSIS

Read in the Section on Diseases of Children, at the Thirty-Eighth Annual Meeting of the American Medical Association, June, 1887

BY WILLIAM S STEWART, A M, M D,

PROFESSOR OF OBSTETRICS AND CLINICAL GYNÆCOLOGY IN THE MEDICO CHIRURGICAL COLLEGE, OF PHILADELPHIA, PA

The condition known as congenital phimosis, a contraction of the prepuce over the glans penis attended by inability of retraction, has of late called the attention of the profession to the fact of its very frequent occurrence, and being a source of discomfort and suffering and evil to the young victim

The distress resulting from such condition continues until the force of erection of the organ involved overcomes the unnatural resistance

The evidence of this is exhibited in the fact that most male children during their infancy are more irritable in disposition, nervous in temperament, and difficult of management than females during the same period

In general, when there is a disturbance of any part of the body the child's hand is instinctively applied to that part, so great is the distress in this condition that he early begins to manipulate his penis, applying his hand to the organ in your presence, and for this offense his mother will perhaps rebuke or chastise him as she has frequently done, without for one moment considering that it is the natural result of a morbid condition and not due to a depraved disposition

On investigating the condition of one of these little sufferers we find a muzzled glans, the preputial mucous membrane adhering to its entire surface with here and there embedded between them small, hard and irritating substances of a cheesy consistence, while back of the corona there is a larger accumulation

On attempting to retract the prepuce as far as possible, its opening is found contracted to about the size of a pin's head

This condition is so aggravating as to result in a desire upon the child's part to urinate frequently, and causes the napkin to be constantly wet, while the penis and surrounding parts are irritated and inflamed

Examining the organ more thoroughly you will invariably find that the meatus is red and inflamed as a result of the condition referred to, there is also a scalding on urinating and the little victim will invariably cry out in the agony of the act, which will by and by attract the attention of the nurse, who, in her ignorance of the functions of the various parts of the body, will infer that the child's kidneys are affected This fact being reported to the physician he, in his thoughtlessness, would most likely attribute it to acidity and treat it accordingly giving only temporary relief

It is not, however, the difficulty of micturition or the accompanying pain which is to be considered, but the effect upon the general system of the pent up penis struggling for liberty, erecting and re erecting until it finally succeeds in overcoming the difficulty, or, until the habit of self abuse with all its debasing and debilitating effects is brought on

No doubt if careful observation were made many other serious attacks might be traced through reflex influence to this congenital condition

Convulsions, which are so likely to occur during the early months of childhood, and are wholly attributed to the effects of teething, indigestion and intestinal worms, will prove by closer observation to be due, at least at times, to the excessive irritation resulting from phimosis

Paralysis of infancy, has by still further investigation been traced to the same cause, and such has been the experience of the orthopœdic surgeon that when from almost any cause a child is brought under his care for nervous affections of any part of the body, the little fellow is examined as to the condition of the foreskin, and if it be not satisfactorily relaxed the first step in his treatment is circumcision

I recall a most interesting case in which a child had been in convulsions for several days and under treatment by a reputable physician, who, with his bromides and chloral, was unable to afford permanent relief When called to see him I found one side of his body paralyzed, and his power of speech gone, and still everything in the way of remedies had been assidiously given

On inquiring into the history of the little fellow's treatment what surprised me most was that, on removing the napkin the mother did not direct the attention of the careless doctor to the condition of the child's penis as it was swollen and inflamed and on the slightest pressure there exuded a quantity of disintegrated smegma The relief obtained by treatment of the organ gave most satisfactory evidence as to the influence of the occult cause in producing persistent convulsions

Although an apparent paralysis had been established and the spasms were still uncontrolled, after operating upon the child and administering the iodide and bromide of potash internally the little fellow made a rapid recovery, the paralysis disappeared, his speech returned, and he did not have another convulsion from the time of the operation

Now, as to the method of operating Circumcision as a religious rite has been practiced by the Jews since the days of Abraham Why it should have been imposed upon that nationality as a religious ceremony was probably the fact of the necessity But as such a rite was not enjoined for the Christian dispensation we are not obliged to follow any prescribed Mosaic or Christian law, but be a law unto ourselves

It is the method of operating that interests me most in appearing before you at this time, the idea of using the knife in removing any part of the body is still so repulsive to our fellow *gentile* race and particularly repugnant to parents, and especially mothers, that in order to meet this prejudice, I have been led to devise the following plan of treatment, and that you may better understand the philosophy of my method, let me first explain to you the condition of the parts

The trouble involved is due to a contraction of the mucous membrane of the prepuce, the skin being lax

and sufficiently free On careful examination you will find the mucous membrane adhering closely to the entire surface of the glans penis When circumcision is performed the cutting off of the redundant foreskin does not remedy this trouble referred to, nor can the prepuce be retracted without first tearing or splitting up the mucous membrane

What is sought after for the health and comfort of the boy is easy retraction of the prepuce so that cleanliness of the organ can be secured, and all irritating matter that has accumulated around the corona may be removed

This I have found by experiment can readily be accomplished almost invariably as a bloodless operation, by a careful stretching of the mucous membrane with an instrument that I have devised for the purpose, which with its four expanding blades stretches the parts equally and at the same time gradually breaking up the adhesions until we uncover the anterior portion of the glans, when we are obliged to resort to the blunt end of a probe to dissect off from the glans as far back as the corona the tightly adherent membrane

On so doing we will come across here and there over the glans small particles of hard granular substances about the size of a pin's head which have become embedded between the mucous membrane and the glans, acting as foreign bodies, and of course a source of great discomfort When the corona is reached we generally find a layer of smegma filling the entire indenture of this part of the organ This carefully removed, the parts oiled with some wholesome unguent, and the foreskin drawn forward the operation is complete, without a drop or at the most with only a few drops of blood, and without the necessity of a stitch or the application of any special dressing

I will endeavor to give you an ocular demonstration of my method of procedure in this operation First, as the operation is only momentary I will not require to subject the child to the risk of an anæsthetic But as a substitute I sometimes use a 10 per cent solution of cocaine, applying it over the mouth of the prepuce, which results in a painless operation After the cocaine has taken effect having placed the boy on his back on a table, we will take our position on the right side of the boy and table and with left thumb and forefinger we will grasp the side of the prepuce whilst we take the instrument in the right hand The assistant will stand on the opposite side of the table, and will also grasp the opposite side of the prepuce and stretch it upwards and apart as much as possible to enable the instrument to be inserted into the opening Having passed the instrument as far as possible into the orifice of the prepuce we must be careful to avoid the meatus as the urethra might be lacerated by mistake In expanding the blades of the instrument, which I have named the 'Preputial Dilator," much care must be exercised in order that the prepuce is not too suddenly and extensively stretched, so as to avoid tearing either mucous membrane or skin, for if such should happen the success of the operation is not nearly so satisfactory It would be much better to repeat the process cautiously from time to time until thoroughly accomplished, than to be rash at the first, as it is very evident that during the healing process the tendency of the parts is to contract and therefore reestablish the original trouble

EFFECTS OF OBLIQUITY OF THE CORRECTING LENS TO THE VISUAL AXIS

Read in the Section on Ophthalmology, Otology and Laryngology, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY EDWARD JACKSON, A M, M D,

ADJUNCT PROFESSOR OF DISEASES OF THE EYE IN THE PHILADELPHIA POLICLINIC

The effect of a spherical lens upon a pencil of light rays entering it obliquely has been carefully studied by Prof E C Pickering and Dr Charles H Williams, who have recorded the results of their investigations in the *Proceedings of the American Academy of Arts and Sciences*, Vol 10, 1874-5, p 300 Dr G Hay, in a paper "On the Increase of Refractive Power of a Plano Cylindrical Lens when Rotated about its Axis," in the *Transactions of the American Ophthalmological Society* for 1875, p 319, has given the results of a similar study with reference to cylindrical lenses

In these papers the mathematical questions arising in connection with this subject are clearly and exhaustively discussed But the only practical applications made of the law developed, is, in the former paper, a reference to its importance in the correcting of wide angle photographic lenses, and in the latter, the suggestion of an apparatus for the measurement of astigmatism A recent paper on the subject in the *American Journal of Ophthalmology*, by Dr S M Burnett, equally neglects the extremely important practical aspect of the subject

Briefly, the placing of a lens so that the incident pencil of rays enters it obliquely increases its refractive power The cylindrical lens acts simply as a stronger cylindrical lens, but with the spherical lens the increase of refractive power is greatest in the meridian in which the obliquity is measured, so that it comes to act as a sphero cylindrical lens, with one principal meridian in the direction of the obliquity, and the other perpendicular to it Thus, if a convex lens is revolved about a vertical axis so that a pencil of horizontal rays strikes it obliquely, its effect upon the pencil will be that of a stronger convex spherical lens combined with a convex cylindrical lens with its axis vertical

Tables showing the effect of given degrees of obliquity are given by Pickering and Williams I have

confirmed the approximate accuracy of these tables both by calculation and empirical tests They are sufficiently accurate for all practical purposes, with glass having a refractive index 1 54, which is about that of the glass used for spectacle lenses

The following table, based upon the data of Pickering, and Williams, and Hay, gives in the first column the various degrees of obliquity up to 40° In the second is shown the effect on a 1 Diopter cylindrical lens, while the third gives the sphero cylindrical effect of a 1 Diopter spherical lens equally inclined to the axis of the incident pencil

Obliquity of the Lens	Refractive Power of a 1 D Cylindrical Lens so Placed	Sphero Cylindrical Equivalent of a 1 D Spherical Lens so Placed
0°	1 D cyl	1 D spherical
5°	1 01 "	1 00 sph ◯ 0 01 cyl
10°	1 04 "	1 01 sph ◯◯ 0 03 cyl
15°	1 10 "	1 02 sph ◯◯◯ 0 08 cyl
20°	1 17 "	1 04 sph ◯◯◯◯ 0 13 cyl
25°	1 30 "	1 06 sph ◯◯◯◯◯ 0 24 cyl
30°	1 44 "	1 09 sph ◯◯◯◯◯◯ 0 36 cyl
35°	1 69 "	1 12 sph ◯◯◯◯◯◯◯ 0 56 cyl
40°	2 01 "	1 16 sph ◯◯◯◯◯◯◯◯ 0 83 cyl
45°	2 46 "	1 22 sph ◯ 1 24 cyl

It may be noted with reference to this table that the cylindrical effect increases more than the spherical, and that both increase more rapidly the higher the degree of obliquity

For instance, a 10 D spherical lens with an obliquity of 10° shows an accession of spherical refraction of only one tenth of 1 D , and of less than one-third D of cylindrical effect But making the angle three times as great, 30°, the spherical is increased almost 1 D , and the cylindrical amounts to more than three and a half D

Dr Thomas Young proposed to correct his own compound myopic astigmatism by the proper spherical lens placed obliquely before his eye Evidently such an arrangement is only possible when the spherical lens employed is considerably stronger than the cylindrical effect required It has, however, been resorted to from time to time by those using strong convex or concave spherical lenses The device being generally accidentally discovered by the wearer of the glasses, who finds that by holding the object in a certain position, that is, so that his visual axis and the pencil of incident rays shall strike his glass with a certain degree of obliquity, that he can see it more distinctly than anywhere else

Within a month I was consulted by an old gentleman whose left eye was useless, with a pterygium extending on to the inner portion of the cornea of the right He read with a convex 5 D spherical, holding the page very close to his face, and so far to the left that he could barely see it above the bridge of his nose In this way he was able to very nearly correct the 3 50 D of hyperopic astigmatism, axis vertical, which I found on examination This method of correcting astigmatism is, however, quite inferior to the use of the sphero cylindrical lens Because, unless the amount of astigmatism is so slight as to make its correction very unimportant, the glass must be so much inclined that a very slight difference in the inclination will greatly vary the cylindrical effect, making it necessary to always bring the object to a certain position in order to see it clearly, and thus greatly narrowing the available field of vision Suppose a patient had a compound myopic astigmatism requiring for its correction a — 3 s ◯ — 1 cyl axis 180° With such a lens the patient could turn his visual axis 15° from the perpendicular to the lens, either to the left or right, or up or down, giving a field of vision of 30° in any meridian without seriously changing the refractive effect of his glass But if, as myopes not rarely do, he obtained his cylindrical effect by canting the lenses forward, he would have to make their obliquity to the visual axis equal 30°, in which case a deviation of the axis 5° either upward or downward will very greatly impair the accuracy of his correction

When we find a patient who can see better by looking through his glasses obliquely, we should never rest with that correction, but by the aid of the table given above, and careful testing, should search out the sphero-cylindrical equivalent of the obliquely placed lens, and give the patient the benefit of the larger, accurately corrected, visual field, and the lesser liability to transgress its limits

Among systematic writers I believe Landolt alone has directed attention to the importance of care as to details in the mounting of lenses before the eye, and he has by no means exhausted the subject, especially in this direction The greater care to avoid undesired cylindrical effects is of course needed with the stronger lenses For distant vision the lens is to be mounted with its surfaces nearly coincident with the plane of the face, making due allowance for any peculiar habit of position, while for near work, done at a lower level than the eyes, the front surface should look downward and forward

Where a single lens is used for both near and distant vision, its position must lie midway between what would be the best positions for either near or distant visions alone Here the advantages of strongly periscopic lenses would be manifest The perfect periscopic lens, in this respect, would be one having the centres of curvature for both its anterior and posterior surfaces as close as might be to the centre of rotation of the eye Sometimes where the one lens must be habitually used with the visual axis in widely varying positions, it may be worth while even where there is no astigmatism, to add a weak cylinder, with its axis corresponding to the plane in which the visual axis moves, in order to correct the cylindrical effect that will be caused at right angles to this When bifocal or divided lenses are employed their position should also be between the proper positions for near and distant vision But instead of midway between should be much nearer the proper position for the stronger glass Thus with convex bifocals the glass for near work being the stronger, they should look more downward, with concaves the distance glass being the stronger they should look more forward Better still, as has some-

times been done, they may be mounted in a frame which has an angle where the two parts come together, so that each may be given just its proper direction

But perhaps the most important practical lesson to be learned, from a study of the effects of obliquity of the correcting lens, is an illustration of the necessity for accuracy in the determination and correction of ametropia particularly of myopia To place before an eye a lens that does not accurately meet its needs, may by inducing the patient to look obliquely through it, and so to encounter the cylindrical effect, prove quite disastrous for the patient

Chas J, æt 21, came to me recently with evidences of eye strain, headache, pain in the eyes, choroidal congestion and commencing conus He was wearing right and left —4 D spherical that I had ordered for him four years ago and which had been worn most of that time with comfort But he now believed he had some astigmatism, saw with different degrees of distinctness, lines running in different directions *To see clearly objects a little way from him, he would twist his head to one side and look obliquely through his glasses* This maneuver gave him V $= \frac{15}{\infty V}$ mostly, while looking directly forward he saw but $\frac{15}{\infty}$ partly Under a mydriatic his symptoms of eye strain promptly disappeared, it was found that during the four years his myopia had increased 0 75 D in each eye Such an increase may have been due to a strictly physiological development of the globe, but the effort to see clearly with his imperfect correction caused all the symptoms of an aggravated astigmatism The obliquely placed lens caused an astigmatism of the incident pencil which varied continually and allowed the establishment of no constant compensatory accommodative effort

I fear that many ophthalmologists regard it as a small matter to leave a little myopia uncorrected, or think it rather a good thing to do, because it saves a little effort of accommodation I believe that for reasons above indicated it is dangerous, and could detain you longer with the citation of cases that would illustrate and enforce my point As spectacle lenses are usually fitted and mounted, it is quite possible to get by looking through the edge of the lens an obliquity of the incident pencil either upward or downward of 25° or 30°, and to the right or left of from 30° to 40° Now a glance at the table will indicate how much increase of spherical refraction accompanied by astigmatism can be obtained, by such an obliquity, with a strong lens And if, as many, especially Thomson and Green, have argued, astigmatism be especially dangerous to the myope, it cannot be doubted but that the temptation to thus secure better distant vision is also very dangerous

The myope with a partial correction shares this danger, with the presbyope whose glass is insufficient for near work and who strives to shorten its focus by looking through it obliquely, and the two constitute the best and most common examples of the dangers of using lenses not wisely selected

Another very practical application of our knowledge in this direction, is in warning patients, especially such as use strong lenses, always to look through the center of the glass And in this law governing the action of lenses we may find a partial explanation of that difficulty which Landolt so graphically portrays, in satisfying our cataract patients with the optical substitute for the crystalline lens

PATHOLOGICAL CONDITIONS OF THE TEETH AND THEIR SYSTEMIC EFFECTS

Read before the Section of Dental and Oral Surgery, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY K B DAVIS, M D,
OF SPRINGFIELD ILL.

This subject is one of great importance, not only to the dentist but to the oculist and the general practitioner of medicine Important as it is, however, it has not heretofore received that attention from medical writers, and practitioners that it justly merits That pathological conditions of the teeth and the structures adjacent to them in the oral cavity, do exert a most pernicious influence upon the general system, is a fact as well established as any other medical observation Yet I fear there are too many practitioners that almost wholly ignore these conditions as causes of many systemic disturbances

The attention of the profession was recently called to this subject, by the New York *Medical Record*, in which Dr Samuel Sexton, a distinguished oculist and aurist of New York City, and the editor of the *Record*, were the principal writers

The *Medical Record* of October 4, 1884, contains a report from the aural service of Dr Sexton, entitled "Pain in the Ears, due to Irritation in the Jaws" He describes a number of cases of otalgia, in which he found the lesion to be in diseased teeth

The same number of the *Medical Record* contains an editorial on "Dead Teeth in the Jaws," which reads as follows "Perhaps the time is near at hand when medical men should be themselves better informed concerning diseases of the jaws and mouth, rather than refer the ailments of this region to individuals whose limited knowledge of medicine does not prevent them from "treating" dead teeth long after their presence in the jaws has given rise to alveolar abscesses and neuralgias, more or less painful It would not be strange if in the course of events, the day would soon come when all teeth without pulps, and hence, in process of more or less rapid decay, as well as those which the deposit of tarter or other cause, had entirely divested of periosteal nourishment would be promptly condemned as unfit to remain in the jaws—regarded in fact as foreign bodies, liable to give rise, not only to cerebral irritation and diseases in the organs of special sense, through the propagation of local disturbances in the mouth, to the regions mentioned, but to endanger likewise the general health, through purulent matter discharged into the mouth from alveolar abscesses, to be continuously swallowed for a long time, or, indeed, in some instances, to be absorbed, and thus produce septicæmic poisoning It is certainly grati-

fying to note the establishment of instruction in oral surgery in some of the schools, and it is to be hoped that this subject will receive the attention its importance demands "

Considering the peculiar structure of the teeth and their relation through the nervous system to the general organization, the close connection existing between the teeth, the rapidity with which the flash of sympathetic pain darts along the nervous cords which vitalizes them, the intolerable and protracted suffering which ensues, upon even trifling irritation of these sensitive filaments, and remember that pain itself is fully capable of deranging the whole economy, and inducing serious and fatal disorders, we might, without the aid of much reflection, adopt the very rational conclusion that the diseases of the teeth must be of considerable consequence to the entire organization We must also remember that the teeth were not made merely for ornament, but to perform certain specific functions, chief of which is mastication and insalivation, and that these are something more than mere forms of introduction to the stomach, that they are important to digestion, which is important to the entireness of organs, and the performance of function, and that if mastication and the insalivation accompanying it be imperfectly performed, some corresponding imperfection of digestion must result We also know the consequences of long continued morbid influences, however unimportant in their immediate action, that disturbance of digestion constantly repeated must sooner or later develop evils of a most serious character

The teeth are not as some seem to suppose, isolated organs, but they have an intimate and vital connection with the whole nervous system, and when the extremities of the nerves are exposed to irritation, whether by wounds of flesh or by decay of the teeth, there is a reaction upon the nervous centres, and various morbid conditions are a necessary consequence

Mastication is doubtless the primary function of the teeth, and should these organs be unable from decay or other morbid causes, to perform this office, the stomach is called upon to perform a double function, that of mastication and digestion, and while thus compelled to do its own work and that of the teeth also, it is much more liable to become disordered, and consequently the whole system may become deranged A stomach treated in this way for a considerable length of time must inevitably suffer But it is possible that some other organ may first indicate functional disturbance But should indigestion ensue from the effects of a morbid condition of the oral cavity, this deranges and impairs the whole system of nutrition and innervation, and sets to work a horrid train of morbid conditions, that render even existence itself almost intolerable

All of us, doubtless, are frequently called upon to witness the mouths of patients whose teeth are nearly all decayed, and many of them afflicted with alveolar abscesses, the gums inflamed and receding, extremely irritable and painful, the glands of the mouth disordered, the breath fetid, the saliva corrupt and extremely unhealthy, the teeth are in such a morbid condition that they cannot masticate their food, but mumble it in their mouths, where it mingles with that corrupt and vicious saliva, and with all the fetid, putrescent accumulations in the cavities of those stumps of teeth, and in this condition it passes into the stomach, where it mingles with the gastric juice, tending to vitiate the whole process of digestion

There are many other morbid conditions either developed or produced by dental irritation Mr Salter, in his Pathology and Surgery, in treating upon this subject, says "The affections of the nervous system dependent on the teeth, divide themselves into those which are reflex, secondary and remote, and those which are direct, immediate and from contiguity In the former category would rank epilepsy, neuralgia, paralysis, in the latter, local pain, facial palsy, some forms of amaurosis, etc In other instances, such as the exalted sensibility of the tegumentary nerves of the face, erratic pains through the maxillary nerves, associated with tooth ache, it might be difficult to say whether the phenomena are mostly reflex or direct, they probably comprise both conditions "

The situation of the teeth, and their abundant supply of nerves, and the great and diffuse swelling which their diseases produce in contiguous structures, inevitably involve much nervous disturbance and complication The inferior molars are but little removed from the tonsils, and Eustachian tube, from the parotid region and the external auditory passage The fangs of the superior molars are close to the orbit, and its all important contents, and more posteriorly they approach the spheno-maxillary fossa and fissure Thus is it easy to account for the nervous complications which are directly entailed by the spread of inflammation from the periosteum of diseased teeth

The several branches of the trigeminus appear to be the most susceptible of reflex affection, caused by dental irritation of one of them, but next to the different elements of the fifth nerve, the branches of the cervical and brachial plexuses are the most commonly involved—pains of the neck, shoulder, acromian process, insertion of the deltoid, bend of the elbow, are by no means uncommon, and with them occasionally a loss of motor power, a weary sense of fatigue in the flexor muscles, and an inability to grasp firmly with the hand

Pain is only one of the phenomena of reflex dental nerve irritation It may induce muscular spasm, *muscular paralysis, paralysis of some of the nerves of special sense, perverted nutrition*

As regards the teeth themselves, which excite this exalted nervous irritability, nearly all their diseases appear capable of causing this condition

Caries with or without exposure of the pulp exostosis, hypertrophy of the cementum, nodular developments of dentine in the pulp cavity, periostitis, plastic or suppurative, impaction of permanent teeth in the maxillary bone, crowding of teeth for want of room

Each and all of the above mentioned pathological conditions of the teeth may and have caused many-

festations of reflex nervous irritation, though they may exist in a severe form without producing any such result

Of the nervous and complicated morbid conditions produced from dental diseases, the following may be mentioned as occurring less frequently than those above mentioned Chronic trismus, epilepsy, tetanus, partial paralysis, amaurosis, deafness, opthalmia, and perverted nutrition

It is not deemed necessary to occupy your time in the narration of cases illustrating the foregoing observations, but I will refer you to the works of Salter, Bond, Garrison, and our periodical literature, where they may be found and read at your leisure

From the foregoing observations, it is surely very important that the physician should never disregard the dental organs as agencies in the production or continuance of diseases, and it should also deeply impress the dental practitioner with the importance of a clear and comprehensive knowledge of the entire organism, both in health and in a diseased condition He should ever bear in mind that his operations are not upon isolated organs merely, but upon organs bearing very intimate and close sympathetic relations to the entire economy

---

PISTOL-SHOT WOUND OF THE ABDOMEN, LAPAROTOMY AND SUTURE OF THE WOUNDED INTESTINES

Read before the Medical Society of Virginia, October 22, 1887,

BY A S PRIDDY, M D,

OF KEYSVILLE, VA

Ras Wimbish, a negro, aged 60 years, was twice shot by his employer, with whom he was engaged in an altercation, on September 4, 1887, about 8 P M, with a Smith & Wesson revolver, 32 calibre, at a distance of six or eight feet The shooting occurred on a farm in Mecklenburg county, about four miles from the town of Chase City The wounded man, at the last discharge of the pistol, exclaimed that he was shot, ran to the stables, mounted a horse, and rode into town where his family lived, "to get a doctor to cut the balls out" Dr C W Walker was called in, and found him falling into a state of profound shock, from which it was several hours before he began to rally He was, after recovering from the shock, very restless, with an anxious countenance, much thirst, pulse quick and weak, and hiccoughed slightly, though vomited none Dr Walker administered ⅓ grain of morphia, and proceeded to examine him

He found that the first shot had entered the fleshy portion of the thigh, and passing through was lodged under the skin on posterior aspect, from which it was easily extracted The second shot had taken effect about one half inch below the anterior superior spine of the ilium, toward the abdomen, the point of entry being small, presenting a jagged appearance, and was sealed with a clot of blood Abdominal palpation revealed nothing wrong, except considerable pain on pressure

He complained of an excruciating pain in abdomen The track of the ball was not fully explored with a metallic probe, as it was quite certain, from its direction, that it had entered the abdominal cavity The man was put to bed and the usual "ostrich plan" of treatment pursued, that is, warm applications to the bowels, and sufficient opium to control pain, to await developments in the case

On the next morning the patient was found to have passed a fairly comfortable night, under opium He had voided a large quantity of clear urine, but his bowels had not moved since the shooting The abdominal pain and tenderness had increased The abdomen had become very tympanitic and emphysematous, which symptoms were attributed to a gaseous distension of the abdominal walls, or of the intestines This condition was of such importance as to make death seem imminent from dyspnœa

Thus things continued dyspnœa, hiccough, occasional retching and vomiting, slightly elevated temperature, and an obstinate constipation, till the third day after the shooting, when a cathartic was given which in due time produced several evacuations, containing considerable blood This made intestinal perforation certain beyond cavil After this the tympanitic condition of the abdomen disappeared considerably for nearly twenty four hours, after which the before mentioned condition again became just as alarming, and so continued

On September 8th, the fourth day after the shooting, Dr F J Gregory, of this place, and I were telegraphed for We arrived about 9 o'clock that night, and found the man in the condition before mentioned, and according to Dr Walker he was growing weaker There were also slight peritonitic symptoms We advised an exploratory incision, with several objects in view first, to relieve the gaseous distension, which was fast causing his death from dyspnœa, to cleanse the cavity of all extravasations and to repair damage to the wounded viscera, and give free drainage, which might lessen his chances of death from suppurative peritonitis, septicæmia, etc, or at least make his time of living more comfortable, and his death one not attended with so much suffering These views were concurred in by Dr Walker, though we thought that the "golden opportunity" had been lost by waiting so long Yet, at earnest solicitation of the wounded man to give him every known chance for his life, however slight that chance might be, we decided on a laparotomy the next morning, provided the man were living

The operation was performed on September 9th, the patient being still alive I made preparations for the operation, which were about as complete as could be made in a *negro cabin*, but not so elegant as some of our well equipped city hospitals afford The instruments were placed in a 5 per cent solution of carbolic acid, and the sponges thoroughly washed out in that solution The hands and nails of all the participants in the operation were cleansed with soap and water, and then dipped in carbolized oil The toilet of the abdomen was made by scouring the walls, shaving the pubes, and washing the whole over with a 5 per cent solution of carbolic

acid, especial attention being paid to the navel and point of entry of the ball

The sponges were next placed in bichloride solution in water 1–1500 Plenty of towels were also provided in same warm solution

At 10 o'clock, in the presence of and assisted by Drs Gregory, Walker, H H Jones, W B Jones, and Mr Ogburn, after the hypodermic administration of ⅓ gr of morphia and 1 100 gr atropia, chloroform was administered and the operation begun An incision was made in the median line from the umbilicus to the symphisis pubis, down to the peritoneum, which was incised after the capillary bleeding had been stopped by pressure with sponges wrung out of hot bichloride solution On opening the peritoneum a considerable quantity of bloody serum, pus, etc , escaped from the cavity, all of which had a distinct and disagreeable fœcal odor, yet there was only a trace of fœcal matter in the cavity I then introduced my hand into the cavity and slowly drew out the intestines, examining each coil carefully till I came to the jejunum, on whose mesentery I noticed a contusion about the size of a silver dime, which was evidently the point at which the force of the ball had spent itself When the descending colon was reached it was found to be lacerated longitudinally for more than six inches, extending into the sigmoid flexure I passed my whole hand through the wound in this intestine, into the rectum The meso colon was also found perforated The intestines were wrapped in towels wrung out of the hot bichloride solution, during the operation, and the normal temperature preserved so far as possible

The lacerated gut was united by a continuous suture of catgut, which was improvised by soaking a fiddle string in water the night before, and then soaking a while in carbolized oil The abdominal cavity was washed out with the bichloride in water 1–1500, and then thoroughly sponged out

The wounds, both in the gut and mesentery, were packed with iodoform I did not think it necessary to excise the wounded mesentery The intestines, after having been thoroughly cleansed, were returned to the cavity A Nèlaton's soft rubber catheter, No 12, was "nicked" in several places, and introduced into cavity as a drainage tube The abdominal incision was closed with seven sutures of white silk, which included the peritoneum Adhesive strips were then applied to the abdomen The wound was dressed with iodoform, and a large cotton pad covered the whole abdomen

The operation lasted about fifty five minutes, which was a rather shorter time than I intended to take, but the man came near dying under the operation, and was only stimulated by several hypodermic injections of arom spts ammonia and brandy, and, with a little speed in the operation on my part, came out very well He was immediately put to bed, and hot rocks applied to his extremities and epigastrium Whiskey or brandy were given freely, and in due time reaction came on freely He was ordered milk and raw eggs for food, and this food *alone*, with stimulants of whiskey or brandy when needed Morphia in ¼ gr doses was ordered every three or four hours, to control pain and lock up his bowels

At 3 o'clock P M that day his temperature was 100°, pulse 110, respiration normal and easy, slight hiccough, no tympanites, lays with legs extended, suffered little pain

Sept 10, 8 A M —Seen by Dr Walker Temperature 100°, pulse 135 Tongue coated, anxious countenance, no peritonitic symptoms Spent a moderately comfortable night under morphia Think he may live through to day Dr Walker was summoned before the court to testify in the case and did not see him again until 6 P M , when he found him almost completely exhausted, pulse about 180, no volume, and scarcely perceptible Skin bathed in a cold, clammy sweat, extremities very cold Did not think it possible for him to live through the night Ordered milk and whiskey every few minutes through the night, and hot rocks to his feet

Sept 11, 8 A M —Seen by Dr W , who found a marked improvement in his condition, had spent a very comfortable night when not taking the nourishment Temperature normal, pulse 135 respiration free and easy, extremities warm No peritonitis Could turn over in bed Took nourishment of milk and whiskey regularly and with apparent relish Some little colicky pains in abdomen relieved by morphia He continued to do well throughout the day, and took a supper of rice, contrary to our directions

Sept 12, 8 A M —Rested well last night under morphia Temperature normal, pulse 120, with good volume Tongue clean, no peritonitis, suffering no pain , the abdominal wound suppurating quite freely, drainage-tube doing good work

6 P M —Dr Walker found him doing well No change in condition except that he had a large solid evacuation of the bowels, which caused very little pain or tenesmus, contained no blood nor mucus

Sept 13, 8 A M —Seen by me for the first time since the operation Found him comparatively comfortable, temperature normal, pulse 100, full and strong Could turn over in bed or lie on either side Kept flies off himself I removed the dressings from the abdomen and found that the abdominal wound had united entirely down to fourth suture Washed the abdomen off with carbolized water and applied clean cotton, after dressing the wound with iodoform He did well the whole day

Sept 14, 8 A M —Seen by Dr Walker Rested well the night before with ¼ gr morphia Had taken sufficient food of milk and eggs Temperature normal, pulse 100, good volume, had a solid evacuation, which griped him considerably

Sept 15, 8 A M —Did not take any morphia last night, and spent quite a restless night Some little tenderness over bowels, but doing well in other respects Left a dose of morphia for him to take at night

Sept 16, 8 A M —Seen by Dr Walker Rested well last night Comfortable, pulse 100, temperature normal, tongue glazed and red, extremities a little cold Noticed a continuous discharge, of a muco purulent nature, from the anus

Sept 17, 8 A M —Seen by Dr Walker and me Found him beginning to show some signs of exhaustion Pulse 110 and feeble, temperature subnormal, extremities rather cold, all of which symptoms were due to the poor attention to his food and other nursing, which his ignorant and indifferent family gave Dr W B Jones consented to nurse and feed him properly, which he did, and marked improvement at once followed

Sept 19, 8 A M —Doing well Wound entirely united Removed drainage tube and took out all of the sutures and applied adhesive strips Takes food of milk, eggs, peptonized beef, soups, etc

Sept 20 —Doing well, and from this time the improvement was steady and uneventful, he being able to take solid food Sleeps well and has sat up on one or two occasions The point of entry of bullet commenced suppurating about October 1, and was very superficial, being due to some little foreign substance being carried in, and was relieved by syringing the hole out with a 3 per cent solution of carbolic acid in water

I saw him on October 12, which was a few days prior to the writing of this report, and found him, to all outward appearances, entirely well of the wound and the operation, but feeble, and suffering at the time from an attack of diarrhœa which, I think, was in no way dependent on the wound, but rather to be attributed to some improper article of food given him, and to bad nursing in general His age, 60 years, the poor attention paid him by his family, who are entirely indifferent as to his ultimate recovery, and the confinement in the house and bed, tend to make his recovery of former strength and activity necessarily slow But as I have said before, at this time, nearly six weeks after the shooting, he is practically well of the injury

Remarks —Although the profession is much interested in this branch of surgery, yet the literature on it is of necessity very meagre, for it was only in 1881, that Dr R A Kinloch, of Charleston, S C, first performed laparotomy for gunshot wounds of the abdomen, and only in 1883, that Kocher, of Berne, and 1884 that Dr W T Bull, of New York, performed the first two successful cases on record I have not mentioned the case reported and recorded in the "Medical and Surgical History of the War of the Rebellion," which Dr Kinloch performed in 1863 on a confederate soldier for a gunshot wound sustained seven months previous to the operation, and which was entirely successful, the man living several years after the war, but I think this operation was more for disease than for traumatism, and should so be regarded

Of all the cases of laparotomy reported—and I think there are only fifty seven—I think my case presents some points of interest which are not seen in the others There may have been more viscera injured in some other reported cases, and I think Dr Keen, of Philadelphia, reported last April a case in Vineland, N J, in which the stomach, colon, ileum and kidney were wounded, from which the patient died on the fifteenth day There are also several other cases in which the stomach was perforated, and another in which the liver was wounded

But my case presented a larger wound in the intestine, and was operated on after the fifth day of the injury, and the patient was just being attacked with peritonitis, and of which tended to make the man's chances of recovery infinitesimally small

One remarkable feature in the case is, I think, the very small quantity of fæcal matter found in the cavity, which can be explained by saying that the man ate an early dinner, and had eaten no supper so nearly eight hours had elapsed since the last food was taken, and consequently the contents of the bowels had sought the lowest portion of the tract, and had passed to a part below the site of injury The bowels were evacuated in the early part of that day

My case and the case of Dr Kollock, of Cheraw, S C, are the only two cases that have been operated on in negro cabins, where the surgeon labors under a great many disadvantages The negroes are, as we all know, very ignorant and careless, and good after treatment is from them an impossibility And in the country it is very inconvenient and sometimes impossible for the surgeon to see his patients so often as necessary

I have reported this case merely to show under what unfavorable circumstances this operation may be undertaken, and to what a satisfactory termination it may be brought, for were the man to die now the operation has certainly saved him six or seven weeks of life, when, on the contrary, it would have been impossible for him to have lived but a few hours without the operation, for fœcal extravasation would have been almost sure to have followed, and as I have said before, peritonitis had begun to set in Even if the wounds be of such gravity as to make recovery impossible, as Dr Kinloch well says, "next to the cure of disease we look to the satisfaction coming of a painless death" by this operation The patient will certainly die an almost painless death, which will well repay any one for the trouble and risk in undertaking the operation

I hope that this case, with other reported cases, may encourage any and every physician, whether living in the city or country, to lay aside the old *passive* line of treatment, and offer to a man with any abdominal traumatism *whatever*, the chances for his life offered in this day of antiseptic surgery, and not until he has done this will he be free from all responsibility

---

A CASE OF EXTIRPATION OF THE KIDNEY, WITH REMARKS [1]

BY L H DUNNING, M D,
OF SOUTH BEND IND

The patient, Mrs H, aged 46, underwent the operation of nephrorraphy Oct 30, 1884 The history of this case was published in Feb, 1885 [2] The kidney was fixed at the time of the operation by eight sutures, three of which passed through and included the renal

[1] Read by Title before the Indiana State Medical Society
[2] THE JOURNAL Feb 21, 1885

capsule These latter untied and loosened within the first 24 hours after the operation, and on this account I think the kidney was not firmly anchored However, three months after date of the operation the kidney was movable only to the extent of one inch in a transverse direction

The symptoms for the relief of which nephrorraphy was done, pain and vomiting, were for a time relieved, but after a few months gradually returned, and at the end of one year were more severe than they were before any operative procedure was resorted to During the last year they have progressively increased until they had become so grave as to threaten the life of the patient The pain is located upon the right side in the hypochondrium and right lumbar region and sometimes extends downwards into the right groin and hip The pain is for the most part of a dragging, pulling character, though sharp lancinating pains sometimes shoot through the right side Vomiting occurs three or four times after each meal For the relief of the vomiting every known means at our command has been used including diet, medicine and lavage, all to no avail

The patient has become much emaciated though not bed-ridden The abdominal walls are so much relaxed that the outlines of the lower border of the liver can be easily felt, and the left kidney, though entirely fixed and normal, can be unmistakably and distinctly palpated To this fact numerous physicians of our city will bear testimony as they were invited to examine the patient on account of this rare condition

Frequent examination of the urine had revealed nothing abnormal except that at times it would be scanty and of high specific gravity, and at other times very abundant and of low specific gravity

On Feb 22, 1887, assisted by Drs Hitchcock and Burchard, the kidney was extirpated by the writer Two incisions were employed, one transverse commencing two inches to right of spinal column, and extending four inches in a direction nearly parallel to the twelfth rib, and about one half an inch below it, the other a vertical one beginning at the starting point of the first one and extending downward to the crest of the ileum

By means of these incisions the kidney was easily reached though we experienced some difficulty in keeping the colon out of the way The perirenal adipose tissue was torn through, and the kidney invested by its capsule brought into the incision It was carefully examined for calculus both by touch and with the needle, but none was found The pedicle was tied first with a double ligature, *i e*, one around the ureter and another around the vessels, then a stout ligature including both The pedicle was then cut off next to the kidney and dropped

There being no hæmorrhage the wound was quickly closed by sutures A drainage tube was left in the wound, and an antiseptic dressing applied The patient rallied well, and went on to a speedy recovery For the first few days she was nourished almost entirely by enemas After a few days lime water and milk were given in small quantities and retained After a time beef extract was given, then boiled rice The remaining kidney took the double work thrown upon it and performed it without apparent disturbance The wound healed speedily with little suppuration All circumstances combined to make the patient's recovery both safe and comfortable, so that at the end of four weeks she was able to leave her bed a part of the time

The kidney which was removed was carefully examined by Dr Hitchcock, who reported to the writer that the kidney was normal in every respect except that upon the posterior surface near the external border there was found cicatricial tissue limited to an area one inch long, a quarter of an inch wide and a quarter of an inch deep The weight of the kidney was five ounces The accompanying table is an accurate record of the case for thirty days after the operation It may be found to contain some points of interest, particularly the action of the left kidney

Record of Pulse, Temperature, etc, in a case of Nephrectomy for 30 days after the Operation Patient aged 46 years Operation Feb 22, 1887, 8 30 a m

22, 12 M Temperature 97 5 Pulse 62 Patient rallied somewhat, very drowsy surface warm, considerable nausea, urinated at 8 A M, before operation 4 P M Temp 99 5 Pulse 78 Catheterized and drew 10 oz clear, light straw colored urine, complains of pain, gave tr digitalis gtt j hyoscyamus fld ext gtts ij every 2 hours 8 30 P M Temp 99 Pulse 90 Catheter, urine 6 oz, vomited, considerable pain in hypochondrium Prescribed chloral per rectum and bismuth sub nit per orem

23, 7 30 A M Temp 97 5 Pulse 84 Comfortable night, catheter, 12 oz healthy looking urine, vomits considerable Continued bismuth and chloral and prescribed ox cerium in gr x doses every 2 hours 1 P M Temp 98 5 Pulse 72 6 oz urine, vomited once Rectal alimentation every 4 hours 8 30 P M Temp 98 4 Pulse 78 Catheter, urine 5 oz, sp gr 1020, normal color, looks well, drinks little water Continued enemas, ordered 2 or 3 teaspoonfuls milk and lime water, continued ox cerium

24, 7 30 A M Temp 99 Pulse 79 Urine 17 oz, sp gr 1019, normal color, has taken 3 teaspoonfuls lime water and milk every 2 hours and no vomiting, everything favorable 1 30 P M Temp 98 5 Pulse 69 Catheter, 13 oz urine, no vomiting Enema of one quart water which caused light liquid movement, patient feels well Continued treatment 8 30 P M Temperature 98 8 Pulse 74 17 oz urine, normal, no vomiting

25, 7 30 A M Temp 98 5 Pulse 74 Rested well, 14 oz urine Dressed wound, dressing soiled with bloody serum but not offensive, left in tube 1 30 P M Temp 99 6 Pulse 84 12 oz urine passed voluntarily, some headache, she now takes 4 tablespoonfuls of milk every 2 hours without vomiting 8 P M Temp 98 5 Pulse 80 10 oz urine, normal, nourishment same Ordered cathartic

26, 7 A M Temp 98 5 Pulse 76 14 oz urine More cathartic given 4 45 P M Temp 99 2 Pulse 80 12 oz. urine, sp gr 1018, acid, no albumin nor pus, bowels moved well, no vomiting

27, 8 30 A M Temp 98 Pulse 72 12 oz urine, bowels acted several times, wound dressed, little pus, ½ drachm, removed tube, wound apparently healed except tube track, no vomiting Ordered ℥ iij of milk every 3 hours 5 P M Temp 99 8 Pulse 96 12 oz urine, slight nausea, no vomiting

28 7 30 A M Temp 98 8 Pulse 84 Urine 14 oz, sp gr 1020, acid, normal color, bowels acted last night 4 30 P M Temp 99 5 Pulse 88 Urine 8 oz, 5 ozs milk now swallowed and relished Continued enemas

March 1, 7 30 A M Temp 98 5 Pulse 84. 14 oz. urine, sp gr 1026, more nourishment, no vomiting Removed stitches, wound healed by first intention over four fifths extent

3 Temperature 99 Pulse 84 Patient is taking more nourishment without vomiting and with relish, urine voided in last 24 hours 28 oz, of sp gr 1027, normal in color and odor

5 8 A M Temp 98 2 Pulse 72 18 oz urine during last 24 hours, it is turbid, sp gr 1029, nourishment retained, bowels

constipated Ordered cathartic 6 P M Temp 99 Pulse 84 Cathartic acted, producing 4 copious discharges attended with much pain Gave chloral anodyne to relieve pain and it set up vomiting

7 Temp 98 5 Pulse 74 Patient better, vomiting ceased, 32 oz urine, sp gr 1022, wound healed

8 7 30 Temp 98 5 Pulse 78 32 oz. urine in last 24 hours, bowels moved by enema, nourishment retained, patient looks well

9 Temperature 98 5 Pulse 72 Had headache during night, better to day, 24 oz urine, no appetite.

11 Temp 98 5 Pulse 78 Bowels moved by enema, sat up in bed last night Urine 24 oz

15 Temp 98 5 Pulse 72 Urine abundant, ate egg, toast and milk for dinner and did not vomit, sat up in bed

21 Temp 98 6 Pulse 72 Sits up once a day, walks a little, complains of pain in right hypochondrium, hip and leg, inclined to vomit if she lies upon her right side soon after taking nourishment but at no other time eats well and retains food

Nearly three months have passed since the operation, and it may be of interest to note the condition of the patient at the present time She is up and around the house doing a little light work She takes liberal quantities of milk, eggs and old bread, and seldom vomits if she restricts herself to those articles She has gained several pounds in weight during the last six weeks The remaining kidney does the work of both with apparent ease She complains of considerable pain in the loin, through the scar, and there is some tenderness in the right hypochondrium Except the pain, for which I am at loss to account, her condition is greatly improved and we may truly say that the nephrectomy was to her a decided benefit

One case, be it ever so successful, cannot furnish a rule for action, it can only be suggestive This one is reported in order to add one to the number still too small to definitely settle all important questions growing out of the operation To the writer this has been an exceedingly instructive case, and in meditating upon it he has concluded that its history tends to throw some light upon a few dark points needing illumination

1 A healthy kidney, if movable, may induce an excessive and persistent vomiting which can only be relieved by removing the offending organ Here a carefully regulated diet, medicine, lavage, pads, friction and counter irritants were all used with no avail Nephrectomy stopped the vomiting

2 Nephrorraphy may place the patient in a worse condition than she was before the operation Mrs H suffered more pain and vomited more after the operation for anchoring the kidney than she did before it was done The reason of this the writer thinks can be easily explained When the kidney was exposed for its removal it was found surrounded by an envelope that had the appearance of the normal peri renal adipose tissue, with bands running through it in all directions of a pinkish white, glistening tissue, reminding one of scar or fibrous tissue These bands were undoubted cicatricial tissue or bands of adhesion resulting from the operation of nephrorraphy These bands reached out in all directions from the kidney to the surrounding structures and formed attachments to them This was very apparent in respect to the liver, the colon and the structures posterior to the kidney and it was thought with the duodenum, though not seen Here the writer believes is an explanation of the great amount of pain present notwithstanding the movements of the kidney were much less than they were before it was fixed

Every movement of the kidney beyond certain circumscribed limits caused tension of the bands of adhesion, and if carried far enough pulled upon the colon and under surface of the liver and probably the duodenum

3 In cases similar to the one the writer is here describing it is his belief that some treatment of the peri renal adipose tissue different than that usually employed should be adopted In a preceding paragraph the extensive attachments of this structure and the visible evidence of former inflammation in the structure itself were both stated In the removal of the kidney it is necessary to tear through this tissue and if it be attached by inflammatory adhesions to the capsule proper of the kidney, which it frequently is, extensive injury to the structure must occur which must result in further inflammatory adhesions

Let us bear in mind another fact after the removal of the kidney the cavity thereby left in the investments will be wholly or partly obliterated by the collapsing of its walls, and these walls are made up of the structures under discussion so that there would be bands of adhesion extending in various directions from a central mass In consequence of this the movement of one organ may be felt by a distant organ, or in consequence of the contraction of the cicatricial tissue the liver, transverse colon and duodenum on the right may be brought too closely together or their movements be too much restricted to be compatible with perfect health or freedom from pain The remedy for this possible result may, the writer thinks, be found in the removal of the whole or part of the peri renal adipose tissue In the case of Mrs H this could easily have been done, but that there could possibly be any advantage in this did not occur to the writer Should another opportunity present itself it will be resorted to and the result duly reported

4 In this case the deep sutures used in nephrorraphy undoubtedly passed through the cortical portion of kidney to the depth of ⅛ or ¼ inch and no extensive disease of the organ resulted A small part of the organ was however entirely destroyed, being displaced by cicatricial tissue This result tends to verify the statements made by the writer in a previous article [3] That it is exceedingly difficult in the operation of nephrorraphy to pass the sutures beneath the renal capsule without injuring the cortical portion of the kidney since in this instance great care was used not to injure that structure It tends too to justify the procedure of Morris, who recently reported a case of nephrorraphy in which he passed a deep suture through the capsule and cortical portion of the posterior and upper surface of the kidney, and although albumin appeared for a few days in the urine a permanent fixation and complete recovery resulted

[3] The Journal, Feb 21, 1885

A NEW FORM OF SUTURE PIN FOR USE IN PERINEORRHAPHY

BY J H KELLOGG, M D,

SUPERINTENDENT MEDICAL AND SURGICAL SANITARIUM, BATTLE CREEK, MICH

After employing the old method of operation for the repair of laceration of the perineum in something more than fifty cases, I became satisfied that some method might be devised whereby the patient would be subjected to less suffering, and the surgeon less uneasiness respecting the results The chief cause of pain always seemed to be a swelling of the tissues from the strangulation induced by the wire sutures, which was frequently increased by more or less cutting of the skin in spite of the nicest care in the adjustment of the sutures and avoidance of unnecessary strain I noted that some of our best operators, in their writings upon the subject, referred to this swelling as a necessary result of the operation, and regarded opiates in some form as on this account necessary in the management of cases of this sort This led me to believe the swelling to be due to the plan of operation, and not to any individual fault of my own I found the opium very objectionable, both from its unpleasant after effects, and from its apparent immediate effects in delaying the reparative effort Fearing to make a very radical innovation, and with much timidity, I gradually lessened the number of wire sutures employed, using superficial silk or catgut sutures, until I reduced the wire sutures to one, and this I did not bury in the tissues, but carried through the mucous membrane, exposing it for at least an inch upon the vaginal surface, about one and one-half inches from the introitus vaginæ By thus giving a broad bearing surface, I was pleased to find much less swelling of the parts, and corresponding comfort to the patient, and more speedy union of the tissues Subsequently, I dispensed with the wire suture altogether, except in a case of complete laceration in which from previous unsuccessful operations or from the great length of time which had elapsed since the laceration occurred, there was great scarcity of tissue and difficulty in holding the parts in good coaptation

I had followed this method with most satisfactory results in more than 100 cases, when my attention was called to the form of pin devised by Dr H O Marcy The great advantage secured by the ingenious device of Dr Marcy in securing lateral pressure upon the wound, and wholly preventing the strangulation of the tissues often unavoidable by the old method, was to me at once apparent I had found my own method so satisfactory, in these regards, however, that I continued to employ it until a few weeks ago, when it occurred to me that I would try the pin Being obliged to operate before I could provide myself with one of Dr Marcy's pins, I had a set of pins made for me by a jeweler, using platinum wire, it occurred to me to have them made after what I suppose to be a new fashion, viz, in the form of a hare lip pin with an eye near the point, by means of which the inner extremities of the needle may be secured together by silk or silver wire, and held as closely together as may be required I found that the pins answered the purpose admirably By securing the inner ends of the pins in close proximity, any desired degree of pressure may be made upon the sides of the wound by simply bringing together the outer ends of the pins and securing them by means of silver wire wound first around each pin and then twisted together The advantage which these pins possess in common with other forms of pins used for the same purpose are chiefly these

1 They secure lateral pressure of the wound, thus spreading out the tissues instead of drawing them together, and by this means securing union in such a manner as to produce a thicker and more nearly normal perineum than is ordinarily obtainable by the old method

2 They effectually prevent the swelling of the tissues so constantly present in cases treated by the old method, and thus contribute to the comfort of the patient and diminish the liability to destructive inflammation, and septic poisoning

3 They are not likely to cut or otherwise injure the tissues

I have not used any other form of pin, and hence, cannot speak except from theoretical considerations, but it has seemed to me that the form of pin here presented has at least the following advantages over other forms

1 The readiness with which it may be introduced and secured in position

2 The perfect adjustment of pressure which may be secured Even very severe hæmorrhage may be controlled, as the pressure may be made as great as desired for a few hours subsequent to the operation, being lessened with the greatest facility at any subsequent time as may be considered desirable, by simply separating the outer ends of the pins I have had occasion to perform perineorrhaphy only six times since devising these pins, and hence, my experience with them is as yet very limited, but the results have been so excellent that I hope they may prove to be a serviceable addition to the surgery of the female perineum I may further remark that in the use of the pins I do not rely wholly upon them for holding the wound in coaptation, but carefully join the edges of the mucous membrane and skin by fine silk or catgut sutures, taking pains to cover completely the denuded surface I depend upon the pins to control bleeding and hold the centre of the wound firmly together The pins give little or no pain, and may be removed on the fifth day I have found platinum to be too soft and flexible, and now use steel or brass pins, nickel-plated I fancied that some inconvenience might be experienced by the patient from the points of the pins exposed in the vagina, but have found no complaint of pain from this cause If the direction of these pins is correct they will lie almost parallel with the axis of the vagina, and with the portion exposed in the vagina resting flat upon the posterior vaginal wall

MEDICAL PROGRESS.

SURGICAL TUBERCULOSIS — The fourth division made by VOLKMANN (see the preceding numbers of THE JOURNAL) is *Tuberculosis of Bones, Joints, and Tendon sheaths*

17 Everything that has hitherto been called caries of bones, Padarthrocace, spina ventosa, scrofulous inflammation of joints and bones, tumor albus, fungus articuli, strumous affection of joints (English), in most recent time designated, on Billroth's precedent as fungous inflammation of bones and joints, belongs, with very few exceptions, to genuine tuberculosis

18 As an etiological moment in the origin of chronic suppurative affections of bone and joints, a series of other infectious diseases has to be considered, most of them, however, begin acute, to become chronic only in their farther course The most frequent of these, *infectious osteo myelitis*, often, as we know, leading to suppuration of the joint and destruction of the articular cartilages, presents such a characteristic clinical picture, even when not acute from the beginning nor accompanied by violent symptoms, that diagnostic difficulties can only arise in the more rare form of osteo myelitis epiphysaria, or when the process is localized in the short bones

Cases of joint and bone suppuration in syphilis, rheumatic fever and all kinds of septic infection, are also easily distinguished from the tuberculous forms

In the so called *metastatic inflammations* of joints after acute exanthemata are mainly the cause of difficulty in deciding their character, so soon as they have gone so far as to cause suppuration and destruction of the joint Some of these cases simply mean septic or pyæmic processes, others are undoubtedly tuberculoses, which develop while the acute exanthem still exists, or they closely follow it, and often begin very acute The question is, therefore, how far in acute exanthemata do suppurative and destructive inflammations of the joints exist, really caused by the specific (exanthematic) poison?

19 *Tuberculous affections of joints* start primarily either from the bones or from the synovial membrane,

The primary osseous form is most frequent, particularly in children It begins in the bony epiphyses by the formation of circumscribed tuberculous foci, which remain small, as a rule, and do not exceed the size of a pea or that of a hazelnut Diffuse cheesy infiltrations of a larger area of the spongiosa are much more rare In the beginning, therefore, the trouble is not a joint affection at all, but one of the bone, and may remain as such when the tuberculous foci do not soften or suppurate, or when the foci perforate extra articular instead of into the joint At any rate, the purely osteopathic stage may drag along for an uncertain length of time before the specific affection, the infection of the joint, follows This first occurs when the products of the cheesy degeneration and the tuberculous suppuration of the bone reach into the joint

Tuberculous foci in the spongiosa, particularly in children, have a great tendency to mortify *in toto*, and become separated as characteristic, cheesy, concrement like sequestra The process of demarcation that then takes place has evidently a very good effect, forming as it does a barrier of granulations, the innermost layers of which are found regularly studded with masses of miliary tubercles, which, however, at the same time protect the neighboring bone from further infection Cheesy sequestra and masses of pus found in tuberculous bone cavities only seldom give rise to new (secondary) tuberculous eruptions and infiltrations in the neighboring spongiosa Not infrequently several of these tuberculous osseous foci are present (generally not more than 2 or 3), sometimes in the same epiphysis, sometimes in both articular extremities at the same time They have certain places of predilection, as the olecranon, the iliac portion of the acetabulum, etc., though the relative frequency is not yet decided by exact statistical researches

20 *The primary synovial form of tubercular joint affections* is particularly to be found in adults, and more especially in old people this form prefers certain joints, as the knee for example

The miliary tubercles, which infiltrate the synovialis densely, are developed either with or without simultaneous growth of vessels and granulations In the first case the common fungous form is present, in the second sluggish suppuration of the joint, designated by the older authors as cold abscess of the joints, etc, much more frequently seen in older people, and offers an especially unfavorable prognosis

21 Sometimes larger, isolated knots of tubercles develop in the synovialis, reaching to the size of an almond or even to that of a pigeon's egg, and becoming pediculated may project into the joint The remainder of the synovialis may be free from tubercles from the beginning, but will generally later on become infiltrated with miliary eruptions Even in the last mentioned cases healing is possible after extirpation of the knots and short drainage of the joint

22 An important question is, How far may inflammations (originally not tuberculous) of joints become tuberculous in their further course? At the present time this is known only in the somewhat rare cases of fibrinous synovitis with the formation of rice like bodies (corpuscula oryzoidea), and in cases of chronic hydropsies with hyperplastic growth of fatty masses (With regard to tuberculous affections of joints after distorsion, especially of the hand and foot, see below)

23 Tuberculous inflammations of joints, whether primarily originating from the synovialis or from the bone do not necessarily, even in their gravest forms, lead to extensive defects of the bone (caries sicca) followed by suppuration in the joint and abscesses But sometimes the enormous eruption of tubercles in the tissue of the synovialis causes a copious watery exudation—hydrops tuberculosus —*Langenbeck's Archiv*, Bd 33, Hft 1

FRACTURE OF THE SKULL BY CONTRE COUP —By

PAUL BERGER (Paris) and MLLE A KLUMKE (Paris) This paper contains a minute discussion of a case from which the following conclusions are deduced 1 Independent fractures of the base of the skull, produced at a distance from the point of application of external violence on the skull exist 2 These fractures occupy by preference the orbital prominences, the lesser wings of the sphenoid, and the cribriform plate, they may also involve the petrous portion of the temporal bone 3 They appear to result from the mechanism assigned by Perrin to fractures of the skull by *contre coup* 4 Intra cranial effusions of blood situated between the dura mater and the skull, determined by the rupture of the middle meningeal artery at the level of a fracture, may occupy the lower region of the middle fossa of the skull and be accompanied by no sign of cerebral compression, even when they attain a considerable volume 5 Consecutive to a traumatism, a hæmorrhagic focus may be observed in the cerebral substance, produced by *contre coup* at a point opposite to that where the violence was applied, without its being possible to invoke the displacement of the cerebro spinal fluid as the cause of its production 6 In recent and considerable traumatisms, there may exist a clearly defined aphasia, without there being any appreciable lesion of the convolution of Broca, of the foot of this convolution, or of the convolutions of the island of Reil 7 It is impossible then in case of recent traumatism affecting the skull, to depend either exclusively or even principally upon this symptom, to affirm the desirability of trephining or to determine the point for the application of the instrument —*Revue de chirurgie*, February, 1887 —*Annals of Surgery*, August, 1887

BULLET WOUND OF THE LIVER —At the meeting of the Clinical Society of London, on October 14, DR LEDIARD (Carlisle) contributed this case, which was one in which a constable was shot through the body, at a short distance, whilst pursuing some burglars The bullet entered the right side of the chest, between the seventh and eighth ribs, a little to the outer side of the mammary line Deep collapse resulted, during which the bullet was extracted from the right loin, just over the last rib, and two inches from the spine It was believed that the constable was leaning forward to catch a man in front of him when he received his wound Jaundice supervened, and on the ninth day the extraction-wound in the back discharged a large amount of bile-stained fluid, and continued to do so to a less extent for some weeks Evidence of air in the right pleural cavity to a limited area was also present, and subsequently an empyema formed and discharged freely a large amount of pus through the bronchi Elevation of temperature lasted more or less for fifty eight days, but at the end of three months the patient was convalescent, and had made a complete recovery, being still in the Cumberland police The course of the bullet was, probably, through the convex surface of the liver, the diaphragm being perforated twice, and the lung grazed The presence of bile was ascertained by chemical tests, corroborated by Dr Walker, of Newcastle, public analyst for Carlisle The microscope also gave clear evidence of a wound of the liver tissue The bullet was a large one, and weighed 3½ drachms —*British Medical Journal*, Oct 22, 1887

THE URINE IN TABES DORSALIS —The following facts are set forth by MM LIVON and ALEZAIS as the result of a series of researches on the urine of patients affected with an apyrexial disease of the cord —namely, tabes dorsalis A tendency to diminution of the urea eliminated in the twenty four hours, a diminution in the total daily discharge of phosphoric acid, with a tendency to proportional augmentation of the discharge of earthy phosphates, a great variation in the elimination of chlorine, with a bias in favor of hyperchloruria Intravenous injections of tabetic urines appear to be sufficiently toxic in their action, since it has been found that from twelve to twenty-four cubic centimetres of urine per kilo gramme of body weight of animals was sufficient to kill dogs —*Lancet*, Oct 15, 1887

HÆMOSTATIC MIXTURE —PARVESI recommends the following as a hæmostatic mixture in gynecological operations, as being efficient and non irritating

Sulpho carbolic acid	25 parts
Rectified alcohol	25 "
Benzoic acid	5 "
Tannic acid	5 "
Glycerin	125 "
Rose water	200 "

For local use

Sulpho carbolic acid is composed of sulphuric acid 1 part and carbolic acid ½ part, heated over a water bath for a few moments Dissolve the benzoic acid in the glycerin, and the tannic acid in the alcohol —*Gazette de Gynecologie*, Aug 1, 1887

AXILLARY ADENITIS —It is believed by M Grancher that tubercular diseases of the lungs may, through the mediation of the pleura, infect the ganglia of the axilla This peculiarity does not appear hitherto to have attracted much attention, and it is thought that the occurrence of such axillary adenitis may not be rare The knowledge of these facts is regarded as having much importance, not only from a doctrinal point of view, but also from the standpoint of diagnosis, and M Grancher advises that henceforth every case of phthisis should be examined for axillary swellings, and conversely, that every case of axillary adenitis should be examined for the signs of pulmonary mischief —*Lancet*, Oct 29, 1887

CALOMEL FOR HYPODERMATIC USE —SMIRNOFF uses a mixture of 1 part of calomel and 10 parts of glycerin, put in dark glass bottles, with tight glass stoppers, each bottle containing 30 grains of calomel and 5 drachms of glycerin When to be used the bottle is thoroughly shaken, and the syringe introduced through the wide mouth of the bottle —*Therapeutische Monatshefte*, August, 1887

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

QUARANTINE DOES NOT DEAL WITH THE MOST DANGEROUS DISEASES

Under this head DR HENRY B BAKER, Secretary of the Michigan State Board of Health, sends us the following paragraphs

"Relative to the persons who brought scarlet fever to Sutton's Bay, Mich , and who came on the S S Ohio, reaching New York September 30, 1887, Dr Wm M Smith, Health Officer of the Port of New York, says

"'Developed cases of diphtheria and scarlatina arriving on vessels at this port are removed to Ward's Island It is impossible under the law for the Health Officer or the authorities at Castle Garden to quarantine persons who have been exposed to the contagion of those diseases, consequently the sick on board vessels during the voyage, doubtless, often infect the relatives or those with whom they come in contact, and who carry the latent contagion to interior communities I would be glad if the law allowed those exposed to the contagion of these diseases to be held for observation, as is the case when persons are exposed to the contagion of small pox'

"The instance mentioned above is an illustration of what Dr Smith says—the child having been exposed during the voyage and taken sick with scarlet fever the day after arrival at New York, so the infected child went on its way, to spread scarlet fever In Michigan at least, ten times as many deaths occur from either scarlet fever or diphtheria as from small pox

"Is it not time that the whole subject of quarantine was investigated by the States, and by the United States Government, with a view to protecting the people of this country from the introduction of the really dangerous diseases?"

To the question presented in the last paragraph, we reply that the subject of quarantine and all that relates to the transmission and communication of contagious and infectious diseases from one place or country to another, does most urgently need further investigation, not, however, simply in the light of present popular theories and etiological assumptions, but by an impartial and thorough study of the whole past history of these two most important classes of disease Such study will readily develop two great fundamental facts, namely, 1 that there are both specific contagions and infections that are capable of being transported from one place to another in connection with goods, clothing, food, water and confined air, and thereby be brought in contact with the people of the country to which they have been transported, and 2 that such contagions and infections can only propagate disease in such localities as contain the pabulum and material conditions for their own culture or reproduction And no system of laws or regulations can be devised and enforced that will effectually protect the people of this or any other country from invasions of contagious and infectious diseases that does not equally recognize both these propositions, and exact as much vigilance in keeping every community free from the pabulum on which pathogenic germs feed, as in intercepting their introduction by quarantine and sanitary cordons Until very recently, the latter has absorbed almost the entire attention of Governments so far as relates to measures for preventing the spread of diseases And yet no system of quarantine alone has ever proved effectual in preventing the spread of any one of the important infectious epidemic diseases Neither is is probable that any quarantine alone ever will do so, simply because the contagious or infectious material may be, and often is, carried under conditions that no quarantine officer or other human being can detect its existence or presence

The case of scarlatina that called forth the paragraphs quoted from Dr Baker illustrates this fact The medical inspector certainly could not know that the scarlatina poison was incubating in the child's blood before any symptoms of its existence had developed, and so might one or more passengers have, unbeknown to themselves, some item of infected goods or clothing in their trunks where it remained dormant during the voyage, and how could it be possible for the most vigilant quarantine officer to detect or even suspect which was the infected article? We are not arguing against all forms of quarantine, but only desirous of checking the present tendency to concentrate popular attention too exclusively upon mere quarantine detentions for safety We think a uniform system of thorough inspection of persons and baggage, quarantine detention for isolation of

the sick, when any are found, and complete cleansing and disinfection of everything contaminated, and the guidance of all well persons to such localities as are most free from the pabulum on which infectious germs may feed, would constitute the best possible safeguard against the introduction of dangerous and infectious diseases from one country into another And the more effectually the attention of the people of any city or country can be concentrated upon the work of securing for themselves at all times a good supply of pure air, wholesome water, and an uncontaminated soil, the more secure they will be from the invasion or spread of any infectious disease

THE HÆMO DYNAMICS OF CEREBRAL HÆMORRHAGE

"Is there any situation," asks MR LEONARD BRADDON, "more hopelessly depressing than the attitude of the physician by the bedside of a severe case of cerebral hæmorrhage? So certain of the diagnosis that he seems to view the fatal clot through the very skull, perfectly acquainted with the antecedent pathology and the actual mode of operation of the silent force that, as it leaks, destroys, he yet stands helplessly by, the author only of trivial directions, utterances pathetically oracular"

In an article in the *Lancet*, of October 15, 1887, Mr Braddon calls attention to certain aspects of cerebral hæmorrhage, which, he believes, afford grounds for the adoption of strong and successful modes of treatment We know that at the post-mortem examination of a fatal case of cerebral hæmorrhage the most striking feature is the comparatively enormous amount of blood poured out into the brain tissue, and the force which it has exerted in tearing up the cerebral mass The pressure exerted, thinks Mr Braddon, is simply a matter of hydro-dynamics A drop of blood, and then another, and others, escape into the brain substance, every beat of the heart increases the quantity of fluid in the hydraulic chamber, and the destroying force of the extravasation He calculates the extravasating force of a hæmorrhage 10 mm in diameter, and a tension in the arteriole of 10 mm, at about 5 atmospheres—more than sufficient to tear the brain tissue apart *outside*, though in the skull the resistance may be greater "In any event it is evident (1) that the destructive effect of an intra-cerebral hæmorrhage is due to the hydraulic force of the leakage, (2) that as the disruptive power increases in hydrostatic ratio, every second of time is of paramount importance in treatment, (3) lastly, that there is a hopeful method of treatment" If these views be correct, then every hæmorrhage into the brain should, it seems, be fatal But Mr Braddon believes it to be only an accident, contingent merely on the matter of rupture, that every hæmorrhage into the brain from an arteriole little smaller than one of the perforating arteries is not invariably fatal "But one can imagine that (1) the sources of the smaller hæmorrhages are capillary vessels, (2) that in the case of miliary aneurisms, the redundancy of tissue, and in other ruptures fragments of tissue, or clot, may act in a valve like manner to prevent further leakage, (3) the tendency to early clotting dependent on general (and perhaps unknown local) conditions is, in cerebral as in any other hæmorrhages, the greatest check and natural safeguard against further bleeding"

Admitting the truth of the theory as to the production of the spreading force of the hæmorrhage, the questions with which we are concerned in treatment are, how to check a beginning, and how to relieve the symptoms of a large established extravasation On this theory, every heart beat is a force of danger, and every one that can be restrained is a step towards success In these cases blood pressure means extravasation, and whatever will lower the one will retard the other, says Mr Braddon The horizontal posture, "if it lower the frequency of the beat, increases the blood-pressure within the cranium, the outflow from which gravity, best brought to bear in an upright attitude, especially assists Cold externally means congestion inside Starvation and cold food mean foregoing the immense advantage of attracting as much blood as possible to the portal system, and so lowering the supply elsewhere Narcotics producing sleep, during which the brain is anæmic, could not be certainly injurious, and although of doubtful utility in the presence of better drugs, in their absence opium ought not to be despised, it lowers the blood-pressure and relieves the brain" The giving of purgatives Mr Braddon regards as an open question We know that Trousseau made his patients sit up, take food, and if possible, exercise More important than all else in the way of medical treatment, says Mr Braddon, is the giving of drugs that lower blood tension, such as nitrite of amyl, the nitrites generally, pilocarpine and other tension reducing drugs, and warmth to the hypogastrium and the hot bath

But the simplest, most potent, the most readily applicable, yet most ignored remedy of all, says the author, lies in surgical procedure We cannot reach the lesion, we must, then cut off the supply of blood by applying pressure to the nearest main

trunk When the seat of hæmorrhage is diagnosticated we should compress the carotid on that side, keeping up the pressure for several hours to give the ruptured vessel time to be occluded by a clot In grave cases, and in those in which the seat of the lesion cannot be diagnosticated, both carotids might be compressed When continuous pressure cannot be applied, he thinks the carotid should be tied, though of course this could completely arrest the bleeding when it comes from a branch of the external carotid About three years ago Mr Braddon tried compression of the carotid, and with success

In the more severe and more frequently fatal cases, in which the patient is comatose when first seen, breathing stertorous and slow, pupils dilated, etc., after compression of the carotid, Mr Braddon recommends trephining for the purpose of at once reducing the intra cerebral pressure This was the effect of trephining in a case reported by Mr Howse to the Clinical Society of London, and in a case reported in the *Lancet*, August 20, 1887 When the disc of bone was removed the symptoms were immediately alleviated In this day of cleanly surgery meningitis is not to be feared, and it cannot be regarded as heroic surgery to trephine, pass a trocar, bistoury or probe into the brain substance to reach the mass of blood Increase of hæmorrhage need not be feared, as we well know the effect of the admission of air to bleeding cavities If in this way the surgeon can tide the patient over the immediate danger, and will keep the wound clean, he need have no fear as to the clot—it will be absorbed

TAMPONING THE UTERUS IN HÆMORRHAGE

FRAIPONT calls attention (*Annales de la Societe medico chirurgicale de Liege*) to the value of tamponment of the uterine cavity by means of iodoform gauze in certain cases of severe uterine hæmorrhage The gauze should be used in large pieces, supple and thin, and may be left in the cavity for one, two or three days, the cavity having been washed out with a carbolic acid or sublimate solution Under its use, says Fraipont, there is no retention of secretions and no decomposition If the gauze be well pushed in it serves as a filter to carry off the secretions, which are considerably diminished, and to deodorize and disinfect them The pieces of gauze act as foreign bodies in the uterus, causing it to contract and arrest hæmorrhage

To permit the introduction of the gauze the cervix must of course be dilated Fraipont has made use of the gauze tampon after operations, such as abrasion of hyperplastic mucosa, excision of pedunculated polypi, or enucleation of encapsulated submucous fibromata, in cases of abortion in which the ovum and membranes were expelled or removed, after pathological or normal labors, when hæmorrhage is due to atony of the uterine muscle After every operation on the interior of the uterus Fraipont washes the uterine cavity with a 2 per cent solution of carbolic acid heated to 42° or 44° C Sometimes this is sufficient to momentarily arrest the hæmorrhage, but this generally returns after a quarter of an hour, when the action of the hot water has passed off But to prevent any hæmorrhage, as soon as the solution returns clear the cavity is stuffed with pieces of iodoform gauze A tampon of oakum or tow, impregnated with borated glycerine, is placed against the cervix The vaginal tampon is omitted Duhrssen, of Berlin, (*Centralblatt für Gynakologie*, No 35, 1887) has also used this tampon in two cases of post partum hæmorrhage in which all other measures failed

For the introduction of the tampon the woman is placed in the obstetrical position, the posterior wall of the vagina is exposed by means of a Sims' or Simon's speculum, and the anterior lip of the cervix is seized with bullet forceps and moderately drawn down Several bands of iodoform gauze, an inch wide and about 30 inches long, are ready at hand, the end of one of them is carried into the cervical cavity with a pair of dressing forceps, and it is then gently pushed into the uterus with a uterine sound The outside end is retained at the cervix, and a second piece is introduced until the uterine cavity is filled If there be need of haste larger and larger pieces of gauze are used It may be necessary to repeat the tamponment after 20 or 36 hours, using a smaller quanty, it may be

TRANSACTIONS OF THE NINTH INTERNATIONAL MEDICAL CONGRESS

Knowing that the Executive Committee of the recent International Medical Congress in Washington had made every possible arrangement for the early and proper publication of the Transactions of that body, we recently sent a note to the Secretary-General, who is also Chairman of the Printing Committee, asking what progress was being made, and promptly received the letter given below By its perusal, our readers will see that the work of eleven of the eighteen Sections and of the General Sessions is completed, and either in the hands of the printer or ready to go there, while the manuscript belonging to Sections 7, 9, part of 10, 12, 14, 17, and 18, has

not yet been returned to the Secretary-General It is to be hoped that the officers of these seven Sections will complete their returns as speedily as possible, that the work of the Printing Committee may not be embarrassed and the early appearance of the volumes of Transactions be deferred

WASHINGTON, D C, NOVEMBER 9, 1887

Dr N S Davis,
President late International Medical Congress,
Chicago, Illinois

Dear Doctor —You ask in regard to progress on the "Transactions," and in reply I have to say that the proceedings of the General Sessions, and of Section 1, are all in type, and the type cast Sections 2, (General Surgery), 3, (Military and Naval Surgery), 4, (Obstetrics), and 5, (Gynæcology), are in the hands of the printer Section 6, (Therapeutics, etc), will go forward to day Section 7, (Anatomy), manuscript not received Section 8, (Physiology), ready to send to printer, as soon as Section 7 is in hand Section 9, (Pathology), manuscript not received Section 10, (Diseases of Children), partly received The part on orthopædics, which was delegated to Dr Judson, by Dr Smith, has not been received Section 11, (Ophthalmology), is in hand and ready for the printer Section 12, (Otology), manuscript not received Section 13, (Laryngology), is on hand Section 14, (Dermatology), manuscript not received Section 15, (Hygiene), and 16, (Climatology and Demography), ready to send Section 17, (Psychological Medicine and Diseases of the Nervous System), and 18, (Dental and Oral Surgery), manuscript not received

In regard to reprints the printers have been instructed to furnish authors reprints on such terms as may be agreed between them, but they will not be furnished until the plates have been used for the printing of the "Transactions " Very truly yours,

JOHN B HAMILTON

CONDITION OF THE CROWN PRINCE —The physicians of the Crown Prince Frederick William declared last Monday that the throat affection was cancerous, and that partial removal of the larynx is not advisable, though the physicians at San Remo recommend complete extirpation, which is objected to by the patient

SOCIETY PROCEEDINGS.

MEDICAL SOCIETY OF VIRGINIA

Eighteenth Annual Meeting, held in Richmond, October 18, 19, 20 and 21, 1887

(*Concluded from page 631.*)

WEDNESDAY, OCTOBER 19—SECOND DAY

AFTERNOON SESSION

Dr H M Clarkson, of Haymarket, Va, read a report on *Advances in Obstetrics and Diseases of Women and Children*, that have been established in the last year or two

Dr E M Magruder, of Charlottesville, Va, next read the report on *Advances in Chemistry*

DR HERBERT M NASH, of Norfolk, Va, read a paper on

THE IMPORTANCE OF AN EARLY DIAGNOSIS OF OCCIPI TO POSTERIOR POSITIONS, WITH SUGGESTIONS AS TO THEIR MANAGEMENT

He stated that his paper was not intended as a scientific disquisition on the subject discussed, but a paper, in which he did not enter upon a description of the causes or mechanism of these positions, their frequency being now admitted by most obstetricians, but contended that the vertex did not rotate to the symphisis pubis as often as is believed, that the flexion and rotation of the head should be accomplished by art, and not trusted to chance, and that when the vertex is not thus brought to the symphysis, the labor is rendered protracted and severe, an unnecessary draught made upon the endurance of the mother, and in the primipara the labor otherwise may be dangerous, with great probability of a perineal rupture serious in extent

In cases of labor in the first stage, where the pains are lingering and unsatisfactory, with little or no descent of the head, and especially where there has been an early loss of the waters, he always suspects malposition, and usually finds the large fontanelle at the left acetabulum, with the vertex to the right and rear

If the position cannot now be made out with the index finger, he chloroforms his patient and introduces the whole hand into the pelvic cavity, when all doubt is readily dispelled

If the occiput is found to the right and posterior, he uses preferably the left hand, palm to the head of the child, passing the fingers upwards and backwards over the vertex, pulls down the vertex with the bent fingers, while pushing up the forehead with the ball of the hand After flexion is thus secured he counsels a continuance of the traction, during the prevalence of the pain, by the nails hooked over or onto the projection of the parietal bones (of the child) beyond and over the occipital bone

When the fœtal head is found impacted or immovable, he reinforces this maneuvre by the right hand applied to the lower abdominal wall of the mother, and thus raising the whole uterine mass, and rendering the flexion and rotation of the head feasible by the pelvic hand

When this procedure is accomplished the pains, before futile, now become effectual, and the labor proceeds as in ordinary occipito-anterior positions This mode of practice necessitates an early recognition of the position, and the exercise of some exertion and skill on the part of the accoucheur at the outset of the labor, but saves much suffering and frequently the resort to instruments at a later stage He cites a few cases from consultation practice, merely as instructive, and to show how these positions often annoy and confuse intelligent practitioners

THURSDAY, OCTOBER 20—THIRD DAY

The Secretary presented the *Report on Advances in Surgery*, the author, Dr R C Powell, of Alexandria, Va, being prevented from attending by the illness and death of Dr Albert Fairfax, a Fellow of this Society Dr I S Stone, of Lincoln, Va., read a paper on *Uterine Colic*

CASTRATION NOT THE CURE FOR VENEREAL DESIRE

DR I R GODWIN, of Fincastle, Va., read the *Report on Advances in Anatomy and Physiology* In this report he mentions the case of a male inmate of the Southwestern (Va) Lunatic Asylum, on whom castration was performed for cure of masturbation The operation had been performed several years before he was sent to the asylum Marriage had had no curative effect over his habit, and his wife left him in disgust The operation of castration, done at his own earnest solicitation, had been so thoroughly done that not even a vestige of the scrotum was left But as a result of the castration, not only has there not been a cessation of sexual desire, but he is as capable as ever of erections, and is as capable as ever of having sexual intercourse The sexual orgasm is but slightly obtunded, and the act is completed by the ejection of mucus mixed with the secretions from Cowper's and the prostate glands, and the vesiculæ seminales The desire for masturbation still continues, nocturnal emissions have not ceased, and the man threatens and has attempted suicide It would seem from this case that castration does not destroy sexual desire, nor does it cure masturbation, nor does it produce the desired moral impression that we would expect to have in cases of insanity brought about by masturbation

DR WILLIAM A HAMMOND said that in making eunuchs it was the custom to cut out the testicles and all appendages It is not considered safe to leave even a tenth part of the scrotum or any of its contents And yet with this complete ablation there are instances of the continuation of the venereal desire It cannot be denied that the sexual appetite resides in the brain, but in what part he is unable to say It is well known that criminals in being executed by hanging frequently have seminal emissions This effect no one would pretend to say was due to venereal excitement in the usual sense of the term, but it does show that the centre controlling the discharge of the seminal fluid is to be located high up in the nervous system It is further well known that extirpation of the ovaries does not necessarily diminish the sexual appetite in the female, and these organs must be taken as the analogue of the testicles The testicles and ovaries must be considered, so to speak, as intermediate stations along the nervous track for the discharge of venereal impressions that have previously been received Years ago the Missouri law called for castration as the punishment of rape in certain cases, and yet efforts at rape had been committed by persons who had been castrated for this very crime He mentioned several cases that had come to his knowledge in which the sexual desire did not seem to be materially, if at all, decreased by castration

DR ROBERT BATTEY, of Rome, Ga, in response to the call of the Society upon him for remarks on this subject, stated that his experience had included observation of but one case of the effects of castration in the male During the war, when Gen Sherman was making his historic march to the sea, a colored man was arrested in Middle Georgia for rape The confusion of affairs at the time made it impossible to take the usual legal proceedings in the case Hence under a judgment of his neighbors he was castrated But it did not seem to have the intended effect of destroying his propensity for women, for he continued to have intercourse with any woman with whom he could gratify his passion, each intercourse being gratified by the ejaculation of a discharge Of course it was not seminal fluid, for the secreting organ was entirely removed He has known the sexual appetite to continue likewise in the female after the perfect removal of the ovaries and clitoris Early in his experience as an ovariotomist he announced that "Battey's operation" was not a reliable remedy for nymphomania Some women, indeed, say that their sexual appetite has not been affected by the removal of their ovaries, etc In rare cases, in fact, the extirpation of the ovaries seems to have increased the aphrodisiac nature, but this apparent effect may be easily accounted for by the want of pain which accompanied the marital relation prior to the removal of the ovaries He then cited several cases in illustration It seems to him easy to account for this state of things He still adheres to the views expressed on this subject in 1873 before the Georgia Medical Association He compares the ovaries and testicles, in their developing stage, to a school master, who day by day impresses lessons upon the nervous system or centres As the boy or girl loses his or her teacher, the child does not lose thereby what it has learned, but without further education there is no further development It simply *retains* the impressions already made If the woman had developed the venereal appetite prior to the removal of the ovaries, it is more than probable that that desire will remain after the operation, just about as excitable as it was before the operation He does not, however, believe that it has ever been shown that where the ovaries were removed previous to development of the venereal desire, the woman operated on has ever developed as anything of an aphrodisiac There is no case known to him where the ovaries of a girl have been removed who ever afterwards developed fully as a woman, and he doubts if such a case will ever occur in the experience of any one

The following were then elected

OFFICERS FOR THE ENSUING YEAR

President—Dr Benjamin Blackford, of Lynchburg, Va

Vice Presidents—Drs H M Clarkson, of Haymarket, J Grammer, of Halifax C H, and W D Turner, of Fergusson's Wharf

Recording Secretary—Dr Landon B Edwards, of Richmond

Corresponding Secretary—Dr J F Winn, of Richmond

Treasurer—Dr Richard T Styll, of Hollins

Committee on Publications—Drs C W P Brock, George Ross and Hugh M Taylor, all of Richmond.

Chairman Executive Committee—Dr W W Parker, of Richmond

To deliver the Address to the Public and Profession during the Session of 1888—Dr William T Walker, of Lynchburg

Place of Meeting of the Session of 1888, Norfolk, Va , the time to be sometime in November after the 10th

The following was adopted by a large majority, after the failure of numerous efforts to amend the resolutions as offered by Dr Thomas J Moore, of Richmond

WHEREAS, It has been demonstrated that the provision of the law "Regulating the Practice of Medicine and Surgery" in Virginia, allowing applicants for examination for license to practice in this State to appear during the vacations of the Medical Examining Board before three individual examiners, is a defect in the law, and

WHEREAS, The high mission of the Medical Examining Board of Virginia is seriously hindered thereby, *therefore be it*

Resolved, That the Legislative Committee of this Board, together with a Committee to be appointed by this Society, be requested to petition the Legislature to repeal that provision of the law allowing applicants to appear before three individual examiners

The President appointed Drs Wm S Christian, of Middlesex county, E W Rowe, of Orange county, and J E Chancellor, of Albemarle county, as the Committee on the part of the Society

On presentation by Dr C W P Brock, of Richmond, it was

Resolved, That the Committee appointed on the above resolution be also requested to have the law so amended as to require every candidate appearing before the Medical Examining Board of Virginia, to present a properly attested diploma of graduation in medicine from some regularly chartered medical school or college before he can be entitled to examination

DR J E CHANCELLOR, as a matter of privilege, asked that his resolution of yesterday, asking that the Legislative Committee request the Legislature to so change the existing law as to reduce the number of the Medical Examining Board from 32 of the regular profession to 12, and the homœopathic members in like ratio, be now incorporated as a part of the present proceedings Granted by a vote of 81 to 6

On presentation by DR I R GODWIN, of Fincastle, it was

Resolved, That a Committe be appointed by the President to memorialize the Legislature of Virginia in regard to the fees allowed physicians for examinations of lunatics—the fee at present being only that of any ordinary witness

During recess, DR HUNTER MCGUIRE, by appointment, performed the operation of

SUPRA-PUBIC LITHOTOMY

on a young man Consent was obtained to operate in the Senate Chamber—perhaps the first surgical operation ever performed in the Hall—with a gratifying result up to the date of this report

---

AFTERNOON SESSION

In the absence of the President and Vice President, Dr W D Turner was called to the Chair

DR A S PRIDDY, of Keysville, Va , read a

REPORT OF A CASE OF PISTOL SHOT WOUND OF THE ABDOMEN, TREATED BY LAPAROTOMY AND SUTURING THE WOUNDED INTESTINE

(See p 649)

DR J R SOWERS, of Warrenton, Va , read a

REPORT OF A CASE OF ABDOMINAL SURGERY FOR INTESTINAL OBSTRUCTION,

which had come under his care Man, aged 68, had protracted and obstinate constipation Painful peristaltic actions of the bowels persisted, with gurgling noises Could not precisely locate the pain No very great distension, no fever—in fact temperature a little below normal During the previous three weeks, he had not passed more than a tablespoonful of fœcal matter from his bowels, but had had frequent stercoracious vomitings until within the past few days Previous health good, except an inguinal hernia for the past twenty years, but there was nothing to indicate that the hernia had anything to do with the present trouble Appetite had failed, purgatives had failed, and enemata and the rectal tube did not tend to open his bowels Dr Shirly Carter (the family physician) and Dr Alex Harris both agreed that laparotomy was necessary Dr Sowers made an incision 5 inches long, in median line below the umbilicus Peritoneum opened on a director Not more than a tablespoonful of blood was lost in the operation Passing hand into the abdomen, after careful search, finally found a hard nodulated mass in the small intestine in the right inguinal region It was a coil of ileum adhered to the cæcum and ascending colon by what felt like a sarcomatous growth Another nodulated mass was found in the transverse colon About a half gallon of fluid was in the peritoneal cavity, which was removed by sponges As the pathological condition precluded any relief by surgical measures, the intestines were carefully returned and the incision brought together Nothing notable occurred until the sixth night when he vomited a large quantity of blood—perhaps a quart—and then grew weaker and weaker until he died on the ninth day

DR L ASHTON, of Falmouth, remarked that all cases of visceral wounds of the abdomen should be thoroughly explored, as hæmorrhages, extravasations of fœcal matter, etc , will surely kill unless promptly treated During the past three years, 38 cases of laparotomies for gunshot wounds of the abdomen have been reported with all recoveries Dr Senn reports several cases where the wounds in the bowels had been closed by his decalcified bone plates, and in from 12 to 18 hours, the wounds were found adherent, and closed by plastic material *In regard to*

Lembert's suture, be careful not to put in too many and do not draw them too tight, so as to intercept vascular supply He would use catgut ligatures in stead of silk But whatever sutures one prefers, be careful not to obstruct venous circulation

Dr George Rohe of Baltimore, by invitation, read a paper on

THE VALUE AND PROPER USE OF ARSENIC IN SKIN DISEASES

He cited experiments to show that arsenic modi fies especially the nutrition of tissues derived from epiplastic layer of the embryo, the skin and nervous system The fact that it produces hyperæmia of the skin renders it inappropriate in most cases of acute inflammation, such as *acute* eczema But in *chronic* eczema, especially its papular and scaly forms, and in the pustular form occurring on the face and scalp of strumous children, combined with iron and cod liver oil it is useful In pemphigus, arsenic acts as a specific It is a sovereign remedy also in psoriasis Of course use the local remedies in addition Arsenic acts as a tonic in syphilitic eruptions, but it is of limited value in acne, most cases of the pustular form being made worse by it As an exception, however, it often acts like magic in menstrual acne in young women In the rare disease in this country, lichen ruber arsenic maintains the reputation given it by the elder Hebra Dr Rohe uses in appropriate cases, two preparations arsenious acid in substance, and the solution of arsenite of potash Arsenic often fails to do good until after some preparatory treat ment To children, he generally gives small doses of calomel every three hours for three or four days Then two or three drop doses of Fowler's solution two or three times daily, increasing the dose by a drop or so daily until its physiological effects are pro duced, soon accomplish all the good that it is capa ble of doing The dose is diminished then accord ing to circumstances He rarely continues the mer curial preparatory treatment in adults more than a couple of days, then he gives the following for ten days, the diuretic action of which seems to prepare the system to derive the fullest benefit from the ar senical course

℞ Potassii acetate ℥j
Ext taraxaci fl ℥j
Aquae, q s fit ℥ij

S Teaspoonful in a tumblerful of water, three times a day, a half hour after meals

When ordering arsenious acid in substance, he pre fers tablet triturates of about $\frac{1}{50}$ grain each, more frequently, $\frac{1}{100}$ grain each He generally precedes a dose to be taken between meals by a glass of milk In this way, he has given a ¼ grain of arsenious acid daily for two months without any unfavorable effect He directs Fowler's solution with sherry wine or cinnamon water, or for children, equal parts of simple syrup and cinnamon water As long ago pointed out by Mr Hunt, the smallest toxic dose of arsenic is fifty times as large as the average medi cinal dose Hence the dangerous poisoning by medicinal doses of arsenic is exceedingly remote, and further, cumulative effects need not be feared, as the drug is rapidly eliminated He sums up, that arsenic, properly used, is a most valuable means of combatting certain skin diseases—most prominently, papular eczema, psoriasis, lichen planus, and pem phigus, that when intelligently used it is not toxic, and is harmless, and that it is rapidly eliminated from the system, and hence cannot act cumulatively as a poison Appropriate local treatment is, of course, to be used in every case

Etiology of Zymotic Diseases, was the title of the next paper, presented by Dr M A Rust, of Rich mond, Va Papers were also read, eliciting more or less discussion, by Dr Wm A Hammond, of New York, on *Coca, and the So called Cocaine Habit*, Dr Charles M Shields, of Richmond, Va, on *Advances in Ophthalmology, Otology and Laryngology*, Dr Jo seph A White, of Richmond, on *Sore Throat and Accompanying Nasal Troubles*, Dr G S Conrad, of Mattly Hill Sanitarium on *Moral Insanity*, and cases of some interest were reported by Drs Wm D Hooper, of Liberty, Va, R B Stover, of Richmond and E M Magruder, of Charlottesville

The social events of the Session, were a compli mentary entertainment at the theatre and a banquet by the Medical College of Virginia, receptions by Drs Hunter McGuire, Joseph A White and Charles M Shields, and a banquet by the Profession of the City of Richmond

PHILADELPHIA COUNTY MEDICAL SOCIETY

Stated Meeting, September 28, 1887

The President, J Solis Cohen, M D, in the Chair

(*Concluded from page 636*)

Dr James Collins read a paper reporting some

PECULIAR SEQUELÆ OF MEASLES

Measles is usually considered a very simple affec tion The respiratory organs and eyes are usually watched This being accomplished, and care that aural catarrh is not developed being exercised, measles is considered as having been properly treated During the recent epidemic I witnessed some sequelæ from measles in which the nervous system seemed to be especially involved

Case 1 —A girl of 8 years The fever, eruption, and desquamation followed the usual course, and not until several days after the skin had resumed its normal color, and the bronchitis had disappeared, did the symptoms of chorea develop This child was a blonde, of Irish parentage The invasion of the nervous symptoms was gradual, but they de veloped to a violent degree During the second week the agitation of the child was so great that she could not remain upon a sofa without being guarded or tied She was unable to feed herself, and was constantly laughing and giggling, as well as twitch ing Cimicifuga, tonics, and applications to the spine were used The child recovered and was well at the sixth week

Case 2 —A girl of 11 years, of German parentage,

a dark blonde, also developed chorea, but in a less violent degree Similar treatment was pursued, and recovery was complete in the fourth week

The marked nervous element in these cases causes them to be worthy of note

Case 3—Kate A, aged 3½ years—the second case of measles in the house Eruption appeared at a normal period, and followed the usual course Catarrhal symptoms not more marked than usual Temperature not above 103°, pulse 110 at highest point

On the third day of the eruption she exhibited a peculiar irregular kick while in bed Examination revealed that the reflexes of the ankle and knee were exaggerated, while the ability to stand was greatly impaired, and the coordination of the movements of the lower extremities was imperfect On the following day she was unable to sit up in bed, the arms kept in irregular motion, while the power of grasp was almost lost for small objects By the fourth day, hearing was impaired, and by the seventh day eyesight was lost, and action of the sphincters became uncertain Blind, deaf, and powerless for self help, this poor child for five weeks kept up an idiotic cry, with irregular swinging and aimless motion of arms and legs The special senses gave some objective evidences of such a grave condition The eye-ground showed the arteries tortuous, veins full, choroid congested, disk seemed to be choked in either eye Dr Lautenbach, who is skilled in the use of the ophthalmoscope, assured me, however, that the condition was that of a swollen disk from active inflammation, and not a true choked disk Membrana tympani of both ears normal From a hyperæsthesia of the reflexes there resulted a condition of impaired sensation, with subnormal temperature, as a rule After five weeks under the use of absorbent alteratives, and counter irritation to spine, the child began to improve, and after twelve weeks commenced to walk and see, hearing was slow to return The reflexes of bladder and rectum also became normal Yet the child continued nervous, irritable, howling with raucous voice when disturbed or denied any of her wishes

During the summer she has gradually improved, now walks with gait somewhat wabbling She eats well, sleeps well, and nourishes well Her temper is irascible, she drags the right foot, and falls easily The motion and use of the upper extremities appear to be normal Hearing nearly normal Eye-ground shows evidences of some structural changes, vessels still small and tortuous, some choroiditis remains Vision has improved so that she can distinguish objects, but my last attempt to test it accurately resulted in ignominious failure

Urine has shown neither albumen nor sugar Specimens examined were of normal specific gravity, and deposited phosphates on standing

The following case presents some peculiar conditions

Case 4—Edward L, aged 9 years, had measles in March, 1886 The attack was severe for four days, and in spite of treatment the recovery was slow He complained of severe headache, and of seeing double at times During the spring and summer he seemed to be tolerably well, excepting headache, from which he suffered frequently In July, 1886, his headaches increased At times his head seemed to be drawn either backward or to one side, the paroxysms lasting four or five minutes, after which he would complain of seeing double On closing the left eye, vision improved, at times vomited his food with glairy mucus The lad improved under treatment Spells of headache became less frequent As he complained of his eyes, examination showed hypermetropia of 1 D right eye, 2 D left eye, with astigmatism in left eye The optic disk of left eye swollen, right less so Glasses given in November improved vision, but headache was still persistent at intervals He got along tolerably well until February, 1887, when headache returned with increasing violence, his gait became unsteady, and double vision increased, becoming almost constant

In April he was taken to a specialist, who added prisms to his glasses, which, for a time, improved his vision In May his headaches became violent again, he suffered from attacks of nausea, his gait became more uncertain, he stiffened his feet in walking, and staggered with uncertain movements, frequently falling, but seemed in good spirits, temperature subnormal Urine pale, passed in large quantities, but neither sugar nor albumen detected Since July the lad has lost flesh, loses his food by vomiting frequently, often the matters vomited are undigested food with glairy mucus, of yellowish tinge Pain in head always present before vomiting, head thrown backward, belches, often has hiccough Temperature subnormal, hands and feet usually cold Generally sleeps well

The condition of his eyes as I have seen them, and confirmed by Dr Isett, who is practised in the use of the ophthalmoscope, show both disks swollen, the arteries small and tortuous, veins large, tortuous, choroid congested Dr Isett adds, "no doubt there is pressure on the brain somewhere" The treatment of this lad has been tonic, alterative, and dietetic The case presents a peculiar outcome from measles

I report these to elicit further reports of such cases, and for the sake of calling attention to the effects of measles on the nervous system, which, in these cases, seems to have suffered severely

DR WILLIAM B ATKINSON said During the last epidemic of measles I saw more cases of inflammation of the lungs than in any previous epidemic within the last thirty-five years Catarrhal sequelæ were extremely common I have not met with the eye troubles, nor have I seen any evidences of brain affections I recall two cases, some fifteen years ago, in which the eyes and the brain were so affected that vision was entirely lost In one case the vision returned after a period of fifteen months, and the child recovered perfectly In the second case, that of a child 18 months of age, the vision was perfectly restored at the end of eight or ten weeks I attribute the restoration of vision, in the first case, largely to the use of phosphorus, which, with intervals of rest, was continued for a year

Dr Wm M Welch said I have never met with the sequelæ referred to by Dr Collins, but I believe that reference is made to them in elaborate text-books Such sequelæ are, I think, more frequent after small pox than after measles I have seen the hearing and speech affected during recovery from small pox, but never from measles The author of the paper referred to subnormal temperature after defervescence took place I have noticed this, and also unusual slowness of the pulse In adults I have frequently found the pulse under 50, when in the recumbent posture

Dr E T Bruen said The question whether or not in these cases, where nervous symptoms have been prominent, there is any lesion of the nervous system, has always been an interesting question to me I recently had the opportunity of making a post mortem examination in a case of typhoid fever where nervous symptoms had been well marked from the second week onward The patient had always been regarded as an hysterical individual There was spasm of the muscles of the back of the neck, with retraction of the head to the right side Also spasm of the right arm, with contraction of the muscles, and the right leg was similarly affected The pupils always responded to light, and there was no paralysis of any muscle The patient died, and in my absence the post mortem examination was made by Dr Musser The only abnormal condition found in the brain was the presence of two cysts, one in each fissure of Sylvius These were about the size of a walnut They contained clear fluid There was no evidence of inflammation or of the presence of hydatids It is a question whether or not these cysts were congenital This case shows that there may be marked nervous symptoms without special lesions, and at the same time may we not imagine that some of these cases of severe nervous symptoms in the course of the specific fevers may occur in consequence of imperfect development of the cerebral substance? The only case in which I can recall symptoms similar to those described by Dr Collins was in a child 4 years of age, and the result of this case was permanent insanity

Dr J H Musser reported some

CASES OF PURPURA HÆMORRHAGICA AND LEUCOCYTHEMIA FROM PRIVATE PRACTICE

Case 1 —Middle aged female, free from the hæmorrhagic diathesis, in her usual health, after an attack of gastro enteritis seized with persistent œsophageal hæmorrhage Diagnosis not determined After five weeks, general purpura Death from retro peritoneal hæmorrhage There was difficulty in making a diagnosis until the external evidences of purpura were seen In fact, a provisional diagnosis alone could be made By the absence of hydrochloric acid in the gastric contents, one might presume carcinoma to be present, and yet collateral evidence could not be found to confirm the suspicion Persistent hæmorrhage, without patent anatomical cause, extending over a period of weeks, may be the forerunner of the general hæmorrhage which characterized purpura hæmorrhagica Indeed, it is possible a single leakage causing death from exhaustion, may be the only expression of this grave disease

It is interesting to speculate on the cause of the ulceration found in the œsophagus Was it present before or subsequent to the gastro enteritis? It doubtless was due to thrombus, which might have lodged while the vomiting was in progress

Deaths from purpura are very rare, with the case just detailed, the following may be of interest The recognition of the nature of the disease was easy

Case 2 —F, male child, aged 5 months, fed on condensed milk Never of robust health Skeleton undoubtedly rickety Family history good Never hæmophilia Irregular, disseminated purpuric spots, on trunk and limbs—first appearing two weeks ago Now universal hæmorrhage, considerable exhumation The subcutaneous hæmorrhages were of two kinds—areas of irregular, tender, deep infiltrations, and round and irregular petechiæ, often with a red centre at first In addition, capillary cutaneous oozings were observed A small spot under the skin would break, and a blot clot form on the surface of the skin Several of the points bled continuously, being restrained only by styptics An autopsy could not be obtained

It is to be regretted that in neither of the cases was an examination of the blood made for the microbes of this affection, described by Cheyne

Case 3 —Man, æt 19 General failure of health, marked by a series of severe attacks of illness Final illness characterized by stupor and coma, low delirium, incontinence of urine and fæces, by dyspnœa and cardiac asthenia, by gastro intestinal disturbance, by fever and sweats

The case was of extreme interest All the organs of the body appeared to be normal Septicæmia from pus in some part of the body could not be determined, because the purulent foci could not be found That the cerebral disturbances were not due to renal or hepatic disease was evident Organic brain disease could certainly not have been coincident, on account of the absence of symptoms indicative of such disorders Malarial and lead toxæmia were excluded for want of evidence Unfortunately, the ophthalmoscope was not used Only very late in the illness was the enlargement of the glands in the axilla observed It was then learned that with each period of poor health these glands would enlarge and grow tender The enlargement was not great, however, and could readily have been overlooked The patient was so ill when the hypertrophy was discovered that, in obedience to the friends' wishes, the blood was not examined The diagnosis of the affection, therefore, was not made, because two most valuable instruments of precision, the ophthalmoscope and hæmocytometer, were not used

Case 4 —Rapid enlargement of the lymphatic glands, the liver, and the spleen, in a young boy Enormous increase of white corpuscles, asthenia and anæmia, herpes and subcutaneous hæmorrhages, pneumonia Duration five weeks Diffused tuberculosis of the lymphatic glands and leucocythæmia, alone, were considered in the study of the case After Fagge, we would consider the age, the absence

of fever and emaciation, the enlargement of the liver, the absence of any caseating gland, the rapid course of the disease—all against the likelihood of tuberculosis

The microscopical examination of the sputum did not go for much, as from the nature of things the boy could not cough or expectorate freely, and hence sputum from the lungs was not obtained The physical signs in the lungs might be due to enlarged bronchial glands, although their hypertrophy is rare in leucocythæmia The lad was so ill we could not insist, after the blood examinations, on using the ophthalmoscope Its use would have been of great service Nevertheless, the diagnosis of leucocythæmia we deem quite correct The occurrence of an unusually large crop of herpes labialis was peculiar and instructive The physical signs in the lungs have been spoken of The herpes, the blood stained mucus expectoration, the fever—which subsided in due time—the extreme dyspnœa, and the occurrence of dulness and bronchial breathing taken together, warrant fully the diagnosis of pneumonia, and, we take it, this inflammatory affection complicated the leucocythæmia

DR W D ROBINSON Some time ago I treated some twenty cases of phthisis by the Bergeon method Three or four of these suffered with purpura The purpuric spots rapidly disappeared while this treatment was continued I then made a search for purpuric cases in the penitentiary, and found fifteen These were placed on the use of gaseous enemata, and the spots rapidly disappeared In three cases there was a slight return on the cessation of the treatment, but when the gas was again employed the spots entirely disappeared During the past three months these cases have remained perfectly well I have also had three cases of leucocythæmia, and these have made more decided improvement under the use of gaseous enemata than with any other form of treatment

DR C D F PHILLIPS, of London, Eng, being invited by the President to take part in the discussion, said The speaker has referred to leucocythæmia I should like in this connection to say a word with reference to the action of quinia on the spleen I have found in a large dog that, after the injection of one, two, or three doses of sulphate of quinia into the jugular vein, there is a marked contraction of the spleen, which may continue for two or three hours The blood-pressure rises invariably during the experiment I have also experimented upon the liver, and I think that we shall be able to prove that quinia also produces contraction of the liver I would make one other remark, although it has no bearing on the case reported Caffein is useful in certain forms of congestive headache, and in order to find an explanation of its action in these cases, I removed a large portion of the cranium and dura mater of a dog, and then injected caffein There was a visible contraction of the vessels of the brain In another dog, prepared in the same way, I applied a solution of the caffein directly to the brain, and the contraction of the vessels was much more distinct I think that the beneficial effect of caffein in cases of congestive headache is accounted for by its effect upon the vessels

DR G E DE SCHWEINITZ As is well known, the orange yellow choroid, the broad, pale, often tortuous retinal veins, and the retinal hæmorrhages present in leukæmic retinitis a remarkable picture Some time ago a young colored man came to the hospital complaining of defective vision, which was reduced one half The ophthalmoscope revealed a widespread retinitis, with hæmorrhages, and on account of yellow spots arranged concentrically around the macula, the presence of albumin in the urine, and high tension in the arteries, this was supposed to be a case of albuminuric retinitis The man disappeared for six months, and when he returned a more careful examination of the eye ground cast doubt upon the original diagnosis Dr Osler, too, when the case was referred to him, speedily made a diagnosis of leucocythæmia, and the blood showed a truly extraordinary increase of the white corpuscles The yellow spots in this case were due to a diapedesis of white corpuscles, and not to fatty degeneration, as they are in albuminic retinitis The combination of renal disease with this disorder may lead to retinal appearances identical with those found in primary kidney trouble, in addition to those manifested by leucocythæmia In this case the albumin was due to the pressure of the enormously enlarged spleen I think that Dr Musser might have derived diagnostic aid from the use of the ophthalmoscope in his first case of purpura, because, had he found the retinal hæmorrhages quite common in this affection, the case would have been sharply separated from the hepatic disorder originally suspected The ophthalmoscope, in the hands of Dr Musser and myself, was recently one of the means of leading to a diagnosis of hepatic coma, previously not clearly made out, which diagnosis I confirmed on the post mortem table by finding an atrophic and cirrhotic liver, which weighed less than two pounds I think there can be no doubt that the use of the ophthalmoscope is often quite as important as that of the thermometer or the stethoscope to the general practitioner

DR J P CROZIER GRIFFITHS The case to which Dr De Schweinitz has referred is still under observation in the hospital The spleen is extremely large, filling the whole left side of the abdomen When he was admitted to the hospital the proportion of white corpuscles to red was as 1 4 A later examination showed the proportion to be 1 25 In one case of purpura hæmorrhagica I have carefully examined the blood without finding any microorganisms Culture experiments were not tried

DR J B WALKER I would ask Dr Musser if, in his first case, he used terebinthinate preparations to check the hæmorrhage? I have found, in cases of purpura hæmorrhagica, and in cases of other hæmorrhages from mucous surfaces, that the terebinthinates are very useful These preparations seem to reach all mucous surfaces I have seen several cases of severe hæmorrhage from the intestinal tract, threatening to be fatal, in which the bleeding was apparently arrested by the use of turpentine, after astringents had failed

Dr S Solis Cohen I have had an experience with a case of typhoid fever which apparently confirms what Dr Walker has said In this case purpuric spots appeared shortly before the occurrence of intestinal hæmorrhage The use of turpentine, after the manner directed by Dr George B Wood, answered an excellent purpose I have seen oil of turpentine, by inhalation and through the mouth, arrest hæmoptysis when ergot had failed

Dr Musser In simple cases of purpura iron has seemed of service In the rheumatic cases salicylate of sodium may be employed Turpentine had been fully tried in the case referred to before I was called When I saw the patient, the stomach was so irritable that very little medicine could be given by the mouth I used the wine of hamamelis, much diluted, and aromatic sulphuric acid, well diluted, but without effect

---

Stated Meeting, October 12, 1887

The President, J Solis Cohen, M D, in the Chair

Dr Van Harlingen read

NOTES ON THREE CASES OF LEPROSY

He brought forward the notes of these cases with the purpose of pointing out the peculiarities of leprosy as it presents itself in the earlier and comparatively mild stages of the disease, and with the view of assisting, in some degree, in familiarizing the profession with its most numerous symptoms The matter is one of practical importance, for there is no question, that the disease is on the increase in this country, and before long we may be called upon to decide what course is to be taken for the protection of the community, and, not less important, the care of the unfortunate victims of this disease In addition to the fact that centres of leprosy exist in Canada, in Minnesota, in Louisiana, and in California, several cases have been reported as occurring *de novo* in American soil in persons who have been born in, and have never left the country Under these circumstances it behooves each member of the profession to ascertain and make himself familiar with the appearance of leprosy, so as to be able to recognize it at sight, to make up his mind with regard to the contagious character of the disease, and, finally, setting aside all sentiment and ignorant fear of the malady, to do what can be done for its removal Leprosy is, indeed, contagious in my belief and in that of the majority of observers, but contagious in a slow and uncertain manner Therefore we need have no such fear in approaching it as we should have in coming in contact with syphilis, much less any of the contagious exanthemata

Dr H W Stelwagon I hesitate to express a positive opinion regarding a disease which I have seen so little clinically Various views of the etiology of the disease have been held from time to time, and even at the present time these differences prevail It was formerly charged to dietary and climatic influences, but these, as exclusive factors, have been disproven Another view holds that its spread is due entirely to hereditary transmission, but a study of the affection has excluded this as a main etiological cause Later opinions are that the disease is contagious through inoculation, a view that has much in its favor, but this, also, has been disputed by some writers who have been in position to study the disease One fact, that appears to be against this view is, that in Norway where there are from two to three thousand lepers, the number of cases has been steadily decreasing for the last fifteen or twenty years This decrease is due, it is true, in a measure, to the establishment of lazarettos, but not entirely so, for these contain not more than one-third of the whole number of lepers At the present day, therefore, more or less doubt still exists as to the nature of this disease

Dr W Osler The questions with reference to the contagiousness or inheritance of leprosy are, of course, exceedingly interesting Dr Graham, of Toronto, has made an elaborate study of the disease as it occurs at Tracadie, New Brunswick, and has come to the conclusion that the disease is contagious, and that it is not transmitted by inheritance There, as in Norway, the cases have been progressively diminishing in number Certainly, if contagious, it must be so in a very slight degree It is probably not nearly so contagious as ordinary tuberculosis

Dr A Hewson I have seen something of the anæsthetic form of leprosy, and recently resorted to a plan of treatment which I may say was suggested to me by the lecture of the President of the Society on Bergeon's use of gas, as in the treatment of phthisis I resorted to this expedient in a case in which the bacilli were recognized in the skin I applied the mixture of gases to various parts of the skin, especially the lobes of the ears, by means of inverted funnels, for twenty minutes each day There was a perceptible reduction in the induration in the course of twenty four hours, and at the end of ten or twelve days there was such an improvement that one would hardly have recognized him as the same patient I may say in this connection, that I have been treating cases of keratitis with granular lids by means of these applications of the sulphuretted hydrogen and carbonic acid gases together Within twenty four hours there is such a reduction in the swelling and induration that the lids, which before could not be everted, can be examined without difficulty, and the presence of granular lids as the cause of the keratitis demonstrated The application in all such cases proves acceptable to the patient by its characteristic sensation of gentle warmth to be felt in the part

Dr Van Harlingen It may be said that as the cause of the disease lies in bacillar infection, anything that will kill the bacilli will probably benefit the patient Dr Unna, of Hamburg, from a study of certain cases, has come to the conclusion that a great deal of benefit is to be obtained by the application of certain agents which kill the bacilli How far this method will prove effective I do not know That it will prove effective in the anæsthetic form I very much doubt The reason that a patient has

anæsthetic patches is not that the bacilli are in the skin, but that they are deposited in the nerves which supply these patches

DR WHARTON SINKLER read a paper on

MIGRAINE IN CHILDHOOD

Migraine is more common in children than is gen erally realized Popularly the attacks of "sick headache," which many children have, are attributed to disorder of the stomach from some indiscretion in diet, and many physicians hold the same view The fact that migraine is a disease especially likely to begin about the period of puberty has long been recognized, and this point has been insisted upon by Anstie Many children begin to suffer from characteristic attacks as early as 7 or 8 years of age (Eulenberg speaks of a girl who suffered from excessively severe attacks from her fourth year), and continue to have them until adult life is reached, or, indeed, the attacks may continue all through life Still, it is most often the case that when migraine begins in early childhood, it becomes more severe at puberty and ceases by the time full development is attained

The influence of hereditation is seen to a marked degree in migraine, and the affection often seems to be directly handed down from one generation to the next It is transmitted from parent to child, and may follow either the male or female line, descending from father to son or from mother to daughter The children who suffer from migraine often belong to neurotic families, and it is common to find among the near relatives instances of other nervous disorders It is, then, important for us to be on the lookout for migraine in children who belong to families of nervous tendencies I have now under my care for sick headaches a lad of 14 years, whose mother has violent attacks of neuralgia, and one of his sisters is a well marked example of hysteria It is a well-recognized fact that children who suffer from this disease at and before the time of puberty may, in later life, become the subjects of some of the grave neuroses, such as epilepsy or insanity The great value of the early recognition and cure of the disease is, therefore, apparent

In addition to the influence of heredity, there are many other causes which may induce migraine in children The manner in which a child is brought up has much to do with the production of these attacks Improper food, bad atmosphere, and above all, an insufficient amount of sleep with overtaxing of the brain, all tend to predispose to or directly bring on migraine When a child first begins school he often complains of more or less headache The close air of the school room and too little exercise are enough to account for some of these headaches

In other children, mere mental effort brings on attacks of pain in the head The same thing holds good of migraine that I have observed in chorea, namely, that it is the studious, ambitious children, who stand at or near the head of their classses, who suffer from both of these affections In many instances there are ocular defects, which cause eyestrain, and in these cases the attacks of migraine continue to become more and more frequent in proportion as the eyes are used, until the eye defect is corrected by glasses It is not in all cases, however, that the headaches which follow excessive use of the eyes are due to ocular defect Migraine from eye-strain is not uncommon in children Dr de Schweinitz has kindly furnished me with a case, which is also of interest on account of the superficial optic neuritis which exists

Migraine does not appear to affect one sex more than the other, but if any difference does exist the preponderance is in boys Precocious sexual development in either sex often leads to this form of headache It is astonishing at what an early age evidences of sexual irritation may appear Bad associations and influences lead a child into thoughts and practices that are unwholesome in the extreme and bring about disorders of the whole nervous system Even before puberty the nervous system undergoes a preparatory change, and if there be evil conditions in the surroundings of a child to excite sexual irritation, puberty is hurried forward Under these influences a child becomes hypochondriacal and mopy, complains of various ailments—some of which are real and some fancied—and may suffer from real neuralgias It is very seldom that we meet with migraine in robust and hearty children, but it is seen in those who do not get enough fresh air and who are thin and pale, or in children who think and read too much, and who do not romp and play, but prefer to sit with older people and drink in conversation far beyond their years

The symptoms of migraine in young children are not far different from those in adults The attacks are markedly paroxysmal, occurring from two to six weeks apart, and become more or less frequent, according as the conditions for their development are favorable or otherwise There may be only one or two attacks a year. The attacks may be preceded by premonitory symptoms, such as chilliness, and a feeling of lassitude, and the child is dull, and indisposed to play Sometimes there are subjective ocular symptoms in the form of specks floating before the eyes, muscæ volitantes, or balls of fire, and bright zig zags Occasionally the child complains of hæmiopia These symptoms last a half hour or more, and may be followed by subjective numbness of the tongue, lips, or of the entire half of the body Putnam[1] had a patient in whom in boyhood migraine was represented by repeated attacks of numbness and tingling of the right side of the face, and right half of the body, with aphasia, and hæmianopsia, followed by but trifling headache, or none at all Later in life there were severe attacks of pain Usually as soon as the subjective auras disappear the pain begins At first the pain is dull, and it may be confined to one side of the head, generally, in children, the pain is on both sides of the head, at least they complain of the pain as being general, and it may be either frontal or occipital, most frequently it is frontal Anstie says this is common of all neuralgias of children—*i. e.*, to be frontal and to affect both sides simultaneously

[1] System of American Medicine, vol v, page 1231

There is often nausea throughout the attack, or it may terminate in vomiting, or a free flow of urine, or sometimes there are two or three diarrhœic stools After the crisis is reached the child may fall asleep, and after a nap waken well The attack does not always terminate in a crisis, after a gradually increasing headache for several hours it gradually subsides The face in the beginning of an attack may be pallid, and as the pain increases the face becomes deeply flushed, and the eyes suffused

The treatment must be preventive and curative If a child is of a neurotic family, in which there are already instances of neuralgia and migraine, we should urge the parents to see that he has as wholesome a life as possible Insist on ten hours' sleep a night, and keep him from too prolonged application to his books Six or seven hours of study in the twenty four is enough for a growing child Encourage outdoor sports of all kinds, and, if possible, keep such a child in the country for many months in the year The diet should be abundant and nutritious, milk, eggs, soups, and broths, with meat in moderation, and the various cereals, and plenty of vegetables and fruit Such children can eat largely, and plenty of fatty articles of food is well borne and is of great advantage There is a great tendency, in the education of both girls and boys, to overcramming, and to over stimulation, to reach a high educational standard, but it is encouraging to see the effort which is now being made in our schools to vary and widen the course of study The introduction of manual art into the public schools is of inestimable value to the children, not only because it gives them dexterity and skill in the use of the hands which becomes of practical advantage later in life, but it trains the minds in studies which are, so to speak, external in their kind, As physicians, we cannot too strongly discourage the taking of young children to the theatres, when, not only the late hours and bad air are injurious, but the impressions produced by the plays must be pernicious to an extreme One cannot go to the theatre now without seeing children of all ages looking on at every variety of performance, from the most decolleté spectacular ballet to a melodrama of the highest intensity

If a child has already begun to have attacks of migraine, nothing is of more value than attention to the general health Such children are often pale and thin, and have but little appetite If change of air can be secured, it is often enough to obtain relief from the attacks If we cannot send the patient away, we must resort to tonics and good feeding Cod liver oil, if it can be borne by the stomach, is of the greatest possible use in such cases If the child cannot take oil, we must introduce fat into the system in some other way Cream and plenty of butter may be given Devonshire clotted cream, which is now to be obtained at the Alderney dairies, is relished very much by children

Special anti neuralgia drugs are seldom indicated in these cases, but sometimes the bromides may be given with great advantage, especially in those children who are of a very nervous temperament, and in whom any effort at brain work causes headache It should be given in small doses, and continuously for some weeks

In many cases some ocular defect will be found which will require correction by glasses, and many cases of migraine in children have been cured by this means alone In all cases of migraine we should look carefully into the condition of the teeth, and have any unsound ones filled or removed

DR C M SEITZER said I wish that the author had been more explicit with reference to the dietetic treatment of these cases I infer from his remarks that the majority of his patients have been underfed Most of the cases that I have observed have had an excess of nitrogenous articles, with a lack of sufficient vegetable food I have obtained the best results by limiting the quantity of nitrogenous food, especially in children, and by increasing the quantity of butter, cream, and fatty articles I give light suppers, secure abundant sleep, and moderate exercise, especially in gymnastics Treated in this way, but little medicine is required

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

Colorado Springs and Davos Platz—Beneficial Effects of Evergreen Forests

At the second October meeting of the New York Academy of Medicine Dr Clinton Wagner, who by special experience is well qualified to speak upon the subject, read a paper devoted to a comparison of Colorado Springs and Davos Platz as winter health resorts The change that had taken place in the opinions of a considerable proportion of the profession since the time, a few years since, when warmth and equability were universally regarded as the essential characteristics of a climate adapted for the treatment of phthisis, was forcibly shown, he said, in the present popularity of these two resorts, at one of which, Davos, there was snow on the ground fully half the year, and at the other, Colorado Springs, there was sometimes a difference of 130° between the temperature in the sun during the day and the night temperature

Having described the most prominent features of the two places, he proceeded to point out the differences between them, the advantage being almost always on the side of the American resort Thus, while at Colorado Springs there was an average of 28 good days in the month, at Davos there were only 20 At Colorado Springs there were 8 hours of sunshine in the day, at Davos 4½ At Colorado Springs the invalid could indulge in riding, driving, tennis, picnics, etc , while at Davos the outdoor diversions were confined to skating and tobogganing, which involved too violent exercise for many patients At Colorado Springs he could enjoy the comforts and advantages of home life, if he preferred, while at Davos he was compelled to stay in a hotel, and it was well known that hotels frequented by

many phthisical patients always partook more or less of the character of hospitals and were depressing in their influence At Colorado Springs the patient could remain throughout the year, but at Davos he was obliged to leave early in the spring, on account of the dampness from the melting snow

At Davos, Dr Wagner went on to say, the hotels were excellent, and there was plenty of amusement Formerly the drainage of the place had been very defective, but within the last few years a most efficient system of drainage (said to be the best in Europe) had been introduced As much could not be said for Colorado Springs, where there was at present no public system of drainage whatever, cesspools and old fashioned privies being still in use The principal hotel, however, was very well drained, and he understood that a complete system for the town was now in contemplation With the natural facilities of the place for good drainage he had no doubt that it could be made very perfect On the whole, he would say that while Davos was unquestionably the best high altitude health resort in Europe, the advantages of Colorado Springs were greatly superior in very many respects

Moreover, there were at Manitou conditions very similar to those at Davos, although it was at an altitude more than a thousand feet greater, and the shortest days for the invalid were six hours in length It was well sheltered from the winds, and also possessed some excellent mineral springs At present, however, it was comparatively deserted in winter

In the discussion which followed the reading of the paper Dr Alfred L Loomis said the climatic treatment of phthisis was deservedly growing more and more in favor From his studies in connection with this subject he had learned to recognize that two things were absolutely essential for a curative effect to be produced, and the first of these was a pure atmosphere, an aseptic atmosphere, if one chose to call it so Pure air could be taken into the lungs on the same principle that antiseptics were displayed in external disease and in surgical cases He did not think it was possible to treat tuberculous cavities with antiseptic solutions, and doubted whether inhalations or other forms of applying antiseptic agencies had any real effect upon the lungs But if we could keep these organs bathed in an aseptic atmosphere we were doing all that was in our power to arrest the disease Under the beneficial influences of such an air the temperature became reduced and distressing nervous symptoms were relieved This element must be sought for in whatever locality was selected for the patient Purity of air was naturally to be expected in high altitudes, but the density of the population and various other circumstances might cause its contamination to a greater or less extent He had no doubt that the air of Colorado Springs and Davos had originally been aseptic, but since they had been crowded with hotels and consumptives he feared that this was no longer the case, and he believed that the benefit of residing at these places places would grow less and less until they would finally be altogether abandoned as health resorts

The second essential for a curative effect was the presence of conditions conducive to outdoor life It was simply folly, he thought, for a phthisical patient to go to any resort and spend twenty hours out of the twenty four shut up in a hotel or boarding house It was much better that he should remain at home, for if he were not well enough to take out door exercise, he was not well enough to be sent to these places This was why those in the first stage of phthisis were so often relieved, and the reason that those with cavities lived was because they went to the health resort in a condition enabling them to spend their time out of doors It was, however, not necessary to go to Colorado to find a pure air, and, besides, he did not believe that high altitude of itself was of the slightest practical importance The great desideratum was purity of atmosphere, but as it was desirable that the patient should be in the sun as much as possible, Colorado Springs was to be preferred to Davos As regards recovery in these places, if the patient did not remain in them for two or three years after all trouble had disappeared, the disease was almost certain to redevelop within a few months This was the great objection to high altitudes for consumptives, and he thought it possible to secure a perfectly pure air at a lower altitude, and that, too, much nearer home

The President, Dr Jacobi, having remarked that no reference had been made to ozone, which was claimed to be an important element in the climatic treatment of phthisis, and was found among mountains and evergreen forests, as well as near and on the sea, Dr Loomis spoke of the beneficial effect of antiseptic emanations, and said that many places which were not naturally aseptic were rendered so by such emanations, especially those from evergreen forests

Dr R P Lincoln said that of late there had been a considerable change in professional opinion as to the advisability of sending patients suffering from laryngeal phthisis to high altitudes, and that Dr Solly, of Colorado Springs, had informed him that he had known three cases of this variety of the disease to recover at that resort

In closing the discussion Dr Wagner stated, in answer to Dr Loomis, that he saw no reason why a patient should not be taken to Colorado Springs even if he were not strong enough to take exercise The journey could now be made with comfort in a comparatively few hours, and when he arrived he could sit or ride out in the open air, an advantage which was not available at Davos

At this meeting of the Academy it was voted to form a separate Section of Diseases of Children, the petition for the formation of such a Section being signed by Drs J Lewis Smith, O'Dwyer, and others interested in pediatrics P B P

THE SUDDEN DEATH OF DR J E CHANDLER

REPLY TO DR H C MARKHAM, OF INDEPENDENCE, IOWA

Dear Sir—The facts reported concerning Dr Chandler's disease are too meagre to warrant a positive expression of opinion as to the cause of his

death There are, however, certain considerations which may serve to throw light upon the abrupt termination of his malady Aside from sunstroke, lightning and other forms of traumatism, the causes of instantaneous dissolution may be put down as hæmorrhage into the medulla and paralysis of the heart or, in other words, arrest of the heart in diastole Bulbar hæmorrhage, sufficient to promptly destroy life, must be so copious as to involve the respiratory or cardiac centres, or both, and such a hæmorrhage is extremely rare in the young, and even in the aged is not common Disease of the blood vessels of the part is for the most part essential to its occurrence, and degenerative weakness of the arterial coats is rare in individuals under 40, except from syphilis or prolonged vascular strain in cases of aortic regurgitation Yet, death from bulbar hæmorrhage is so exceptional, even in cases which present the requisite cardiac and vascular conditions, that, even granting the existence of aortic insufficiency in the case of Dr C, the probabilities would be against his death from extravasation of blood into the medulla

When bulbar embolism is the cause of such hæmorrhage, death is usually preceded by well marked symptoms referrable to a profound centric lesion, and Dr C is reported to have fallen to the floor and died without the utterance of a sound Consequently, our inquiry is limited to that other and not infrequent cause of sudden death, abrupt failure of the heart Here we are at once confronted by two considerations, first, that Dr C was supposed to have mitral regurgitation, secondly, that his disease was not thought to present symptoms of special gravity As to the former, as is well known, the usual cause of death in mitral disease is gradual failure of the right side of the heart, and not sudden diastolic paralysis of the left ventricle This latter occurs when compensatory hypertrophy has yielded to dilatation, commonly in cases of fatty degeneration or over distension of the ventricular walls from the force of the regurgitant blood in aortic incompetence There was no autopsy in the case of Dr C and hence our knowledge as to the exact nature of his heart disease, rests on the report of a mitral systolic murmur If one were inclined to be captious, he might doubt the correctness of this diagnosis, if—as is commonly the case—auscultation had been made with the unaided ear and through a portion of the clothing Under such circumstances, a loud systolic murmur heard throughout the præcordia and preceded by a faint first sound, might be mistaken for a mitral systolic murmur, and the first sound for the second sound Had this been the actual state of affairs, his sudden death after the exertion of pulling a tooth might be readily understood

Granting, however, that his disease was in reality mitral regurgitation, his sudden death is not wholly inexplicable, but it must presuppose greater cardiac feebleness and ventricular dilatation than appear to have been recognized Four weeks prior to his death he complained of symptoms referrable to hepatic engorgement, which, although they yielded to treatment, were followed by debility It is not uncommon for patients with heart disease to refer their symptoms to some other organ than the one mainly affected Furthermore, the Doctor was an energetic man, very likely to perform his daily duties without complaint Hence it is reasonable to assume that his condition was far graver than he himself would admit or others recognize It is probable, therefore, that compensation had been ruptured and grave dilatation established In this condition of the heart the physical exertion of pulling a tooth could, by occasioning sudden increase of the arterial tension through muscular contraction and expiratory increase of the intra bronchial atmospheric pressure, cause a degree of ventricular over distension from which the weakened heart could not recover

Although such a sudden death is rare in mitral disease, it is not unknown I have myself lost a patient, the subject of mitral disease, in this way She sat up in bed to drink a cup of tea and suddenly fell back upon her pillow dead

OPIUM INEBRIETY AND INFANTILE MORTALITY

Dear Sir —I am desirous of obtaining facts regarding the relation of opium inebriety in mothers to infantile mortality

Dr Frank B Earle, of Chicago, informed me that he "recently attended a woman taking about twelve grains of morphia daily, who has lost four successive babies between the second and fourth day, all having died in collapse" If any reader of your journal will furnish me details of a similar case, I will much appreciate his courtesy and give him full credit

BOOK REVIEWS.

A PRACTICAL TREATISE ON DISEASES OF THE EYE By DR EDOUARD MEYER, Professor à l'École Pratique de la Faculté de Médecine de Paris, Chevalier of the Legion of Honor, etc Translated, with the assistance of the author, from the Third French Edition, with additions as contained in the Fourth German Edition, by FREELAND FERGUS, M B, Ophthalmic Surgeon Glasgow Royal Infirmary, Assistant Surgeon Glasgow Eye Infirmary With 267 illustrations and 3 colored plates 8vo, pp 647 Philadelphia P Blakiston, Son & Co 1887

Dr Meyer's book is so generally recommended and employed in Germany and France that it is considered the student's text book "par excellence" It has gone through several French and German editions, has been translated into Spanish, Polish, Russian, Italian and Japanese languages We are indebted to Dr Fergus for an English translation, which lies before us Its general arrangement does not differ materially from that usually adhered to by text-book writers Every subject is discussed in

a clear and concise manner The work is abreast of the times Its value is enhanced by the truly excel lent wood cuts, which greatly assist in elucidating the text We do not hesitate in prophesying that the hope expressed by the author will be realized, that "the English edition will prove useful, and find favor with English speaking confrères and students on both sides of the Atlantic"

RECTAL AND ANAL SURGERY, with a Description of the Secret Methods of the Itinerants By EDMUND ANDREWS, M D, LL D, Professor of Clinical Surgery Chicago Medical College, Senior Surgeon Mercy Hospital, and E WYLLYS ANDREWS, A M, M D, Adjunct Professor Clinical Surgery Chicago Medical College, Surgeon to Mercy Hospital With original illustrations 8vo, pp 112 Chicago W T Keener 1887

Dr Andrews is so well known to the readers of this journal, by his frequent and most practical communications, that he needs no introduction to them, and little need be said in regard to the volume before us It is eminently practical and clear, is comprehensive and interesting In the preface Dr Andrews gives a history of the itinerant system, or of the "Piles Doctors" of the country The subject matter is considered in the following chapters

"Examination of the Rectum," "Hæmorrhoids," "Fistula in Ano—Abscess and Sinus," "Fissure and Rectal Ulcers," "Prolapse of Rectum," "Polypus and other Benign Growths," "Mechanical Obstructions," "Malignant Tumors," "Malformation and Pruritis Ani," "Mechanical Injuries" The book can be heartily recommended, and especially for its practical character

MISCELLANEOUS.

SHYLOCK IN CHINA —Dr W Morrison, of Shanghai, China, states that he was called upon to attend a young man whose eyes had been punctured because his father was unable to satisfy the claims of a creditor, on making inquiries, he was informed that the punishment was not uncommon in the district, and that deaths occasionally resulted

$250 PRIZE, COMPETITION OPEN TO ALL THE WORLD — The first award under the William F Jenks Prize Fund, of The College of Physicians of Philadelphia, will be made by the Comm ttee, for the best essay upon the "Diagnosis and Treatment of Extra uterine Pregnancy," as soon after January 1, 1889, as may be practicable Papers for competition must be written in English, and be presented by the said date The prize essay is to become the property of the College By order of "The Committee of the William F Jenks Prize,"

ELWOOD WILSON, *Chairman*

1517 Walnut St, Philadelphia, Pa, U S A

THE DEMAND FOR A THREE YEARS' COURSE OF LECTURES and medical study is becoming so great that it can soon be no longer ignored even by schools which are ambitious of the largest possible classes Recently the Executive Committee of the Alumni Association of Jefferson College adopted the following resolution

WHEREAS, It having come to the knowledge of this Executive Committee of the Alumni Association that four students have gone to the University of Pennsylvania to pursue their medical education, at the recommendation of the Alumni of this College on the ground that Jefferson Medical College did not provide a three years' graded course, and did not furnish clinics or instruction on the special branches of medicine and surgery Be it

Resolved, That the Executive Committee, having the best interest of our Alma Mater at heart, respectfully announce these facts to the Faculty, that they may take such action as they deem best to overcome this apparent growing dissatisfaction of our Alumni —*Medical Record*, Nov 12, 1887

ADDRESSES

SECTION OF LARYNGOLOGY, NINTH INTERNATIONAL MEDICAL CONGRESS

INAUGURAL ADDRESS OF THE PRESIDENT,

W H DALY, M D,

OF PITTSBURG PA

GENTLEMEN —It is gratifying to see so many of my American confrères here to redeem the pledge made for them at Copenhagen, Denmark, in 1884, that an American welcome should be given the International Medical Congress at this, its ninth, meeting It is also a source of highest pleasure to meet those present from foreign lands, many of whose familiar names in the growing literature of Laryngology remind us that we are not altogether new acquaintances With many of us our memories revert at this time, with renewed freshness and pleasure, to our last meeting in the Capital City of the Kingdom of Denmark, the home not only of the sturdy Norseman, but of the most accomplished medical scholars, where both King and Nation gave up their country to the good of the Congress during its meetings, and where every one, from ruler to peasant, united in showing their Nation's guests what the full meaning of the Norseman's hospitality was, so quiet, so restful, so complete that it comes back to us at the end of three years as though it was a quiet happy dream of ours in a Norseman fairy land

We scarcely hope that it is possible for us to be so successful, but if we can secure a degree of the happiness and profit realized by all of us in Denmark, in 1884, then I think we shall have been successful

To one and all, however, not only to personal friends from across the seas, whose familiar faces I see before me, and to whom I am indebted for early and valuable training in laryngology, but to all, I bid a heartfelt greeting and cordial welcome And though we may not attain the perfection of the great meeting at Copenhagen in 1884, yet I beg all of you to feel that the broad bosom of this beautiful land is happy in being your resting place, and its people feel the high honor that is accorded them in being permitted to entertain the worthy representative medical men from foreign nations We sincerely trust that none of you will leave this, our Nation's Capital, without inspecting its resident localities, as well as its public buildings The National Museum, the Museum of the Army, the Smithsonian, and other institutions None of these collections suffer by comparison with the famous collections of the old world In fact, Washington City is, by these institutions, placed in the front rank as a repository of scientific learning

We ought to congratulate ourselves as laryngologists, in this our second meeting as an independent Section of the International Medical Congress, and endeavor to have the work of this branch of medicine placed in every large medical body as an independent Section, as the importance and growing excellence of its literature and valuable practical work deserves

When one looks back to the state of laryngology in 1876, and makes a comparison with the present status of it, it becomes a matter not only of the utmost interest, but of satisfaction and pride to those who have been engaged in its study and advancement, to note what alone its cognate branch, rhinology, has done for the successful and rational treatment of hay fever, which, before the appearance of a paper which I read before the American Laryngological Association in 1881, calling the attention of the profession to some observations I made during a few previous years, upon the local predisposing intranasal causes of this disease, the sufferers therefrom had spent a rambling sort of life in seeking immunity from what they can now, in a large percentage of cases, easily get cured, permanently and surely, at home, by a proper rational treatment

I desire to say, however, that the lamented Hack, and some other able writers in the same field, claimed more for the plan of treatment I then advised than I ever did, as I then, in 1880, assumed to postulate I still find it, after seven years, strongly tenable, viz "Whether we are warranted in believing any case of hay asthma purely a neurosis, without first eliminating the possible causation due to local structural or functional disease in the naso pharynx" Therein clearly admitting that a proportion of cases were of the character of neuroses, but a far greater proportion still depended on a chronic intra nasal disease, upon which the exciting cause, viz, pollen, and other agents, act with effect, and second, without this intrinsic nasal disease the exciting cause is innocuous

I am firmly of the belief that the workers in our special branch will yet make the local treatment so complete that we will cure still a larger percentage, even to all the cases of hay asthma that present themselves This is a hopeful and zealous view of

the future of hay fever, but I nevertheless expect to see this realized

There are few laryngologists but have constant opportunity of observing the rapid development and growth of puny children, after having been under the treatment of the throat specialist, and their noses and throats put in proper order, so that the filthy catarrhal discharges are no longer swallowed, and the upper air passages are opened up so that during sleep they can get a plentiful supply of air, hence physical thrift and comfort quickly change the weakly constitution to a strong one

I think no working laryngologist can fail to note the growing importance of rhinology, and I am free to say the opinion I expressed in a paper before the Eighth International Medical Congress, at Copenhagen, viz, "That the Laryngologist of the future must be more the Rhinologist, and the Rhinologist more the Surgeon than the Physician," has been fully borne out by the evidence afforded by our literature alone

There can be no question that a large proportion of the inflammatory diseases of the larynx are secondary to an initial disease of the intra nasal cavities of a like inflammatory character This I have repeatedly verified by years of observation, and frequently publicly so stated in our deliberations, and I am pleased to say that the number of my colleagues who have since also verified this to their own satisfaction is an ever increasing one, the number containing, as it does, some of the most successful and distinguished practitioners in this special branch of medicine Of the aid modern rhinology has been in our successful prevention and treatment of internal and middle ear diseases alone is scarcely calculable The fact is apparent that no aurist can be accomplished in his special work who ignores the facilities afforded him by a careful study of the concomitant and too often initial disease of the intranasal cavities

But, gentlemen, time passes, and I must not further dilate upon the advancement of our important specialty and its cognate branches, but the bright minds who are now devotees of its service, and future workers, will place it higher and higher, till it reaches its zenith of excellence and usefulness to humanity

As you observe by the printed programme, there are an abundance of papers from able writers from many lands, upon most attractive subjects, and the valuable time of the Section must not be taken up either by your President or any one else to the exclusion of others, I will therefore set the example of brevity by making my address short I feel I have your kind wishes and that you will aid me in expediting the work of the Section from day to day, adhering ourselves strictly to the time permitted to each member under the rules, viz, twenty minutes for the reading of a paper, and ten minutes for each speaker engaging in the discussion thereof, I shall hope that each member will be promptly here at the hour to which we adjourn, so that we can begin our work and continue it without undue haste as the session advances

But, friends, we are solemnly reminded in these living moments, as we enjoy our happy greetings of old friends and new, "from lands of sun to lands of snow," that there too is an increasing number of the goodly names of our honored dead, who worked and won fame in the fields we now cultivate, while they are personally the silent members of this, our Ninth International Medical Congress, yet through every one of you their names and voices and words of wisdom will be heard as you speak at this, for the time being, the World's Medical Forum, to your absent colleagues in every land and clime Their names are on the lips of every student of laryngology, and their words will always stand a part of its growing and valuable literature, and while their fame is our pride, let it also be our aim to emulate the higher traits of character and the ability that won for our Elsburg, Krishaber, Foulis, Bruns, Waldenberg, Buro, Bocker, and Hack, the distinction that made their teachings as beacon lights to guide their less gifted brethren in the fields of laryngological science Oh, honored dead! we in spirit strew flowers on your tombs, and join hand in hand while we bless the memory of your worthy lives, and mourn the events of your too untimely deaths A part of this number were young men, cut off in the growing beauty and strength of manhood, with all the zeal and enthusiasm of their scientific labors still fresh upon them May the earth rest lightly over them in the respective lands where their devoted bodies lie The lamented, the honored dead of our ranks

ORIGINAL ARTICLES.

OBSERVATIONS ON DISPLACEMENT OF THE CRYSTALLINE LENS FROM CONGENITAL AND OTHER CAUSES

Read in Section on Ophthalmology and Otology, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY J L THOMPSON, M D,
OF INDIANAPOLIS IND

Case 1—A L B, æt 17 years, consulted me for glasses some years ago, when it was found that he had displacement of each lens toward the temporal side, with tremulousness of the inner half of the iris A mydriatic was used, after which the inner edge of the lens was to be seen a little to the nasal side of a line dropped vertically through the centre of the pupil With the ophthalmoscope the optic discs seemed to be double, one through the edge of the lens and one in the aphakic portion, which, of course, was due to the prismatic effect of the periphery of the lens Vision in each eye = $\frac{20}{cc}$, with — 6 00 D sph It was evident, though, that the aphakic or inner portion of the eye was hyperopic He was seen four years afterwards, when no change was found in structure, refraction, or acuity of vision

Case 2—W R H, æt 35 (accidentally found to be a cousin of the above), called upon me on December 10, 1884, on account of a terrible neuralgic

pain in the left eye of three weeks' duration It was very much congested, the tension + 2, V = simple perception of light, and the lens was dislocated into the anterior chamber The membrane of Descemmet was partially opaque and striated from contact with the lens, and the iris was dilated and discolored

The condition of the right eye was as follows Lens displaced outwards, just as in case No 1, iridodonesis of the inner portion, and the lens bounded and rebounded outward and backward on the least motion of the eye, settling to the position described above when the organ was at rest The lens of the left eye was replaced after the following method The patient was placed upon a hard lounge, his head was violently shaken, lifted up and thrust backward, several times, but to no effect, pressure was then made upon the cornea with a vulcanite spoon, and by manipulation also through the medium of the lower lid, when, after repeated efforts, reduction was accomplished Eserine was freely used, a pressure bandage applied, and he went to his hotel for the night On the following morning the lens was seen to be behind the iris, which was still widely dilated, tension only slightly above normal He was given a solution of eserine and sent home for a week December 18, pupil still widely dilated, paralyzed, lens behind the iris, and as movable as in the other eye, membrane of Descemmet not so hazy as before V = $\frac{6}{60}$, with — 18 00 D sph In the right eye it = $\frac{10}{60}$, with the same lens He was cautioned about stooping, straining, sneezing, etc, and sent home

On December 28, 1885, one year from the date on which he was first examined, the lens of the other (right) eye became dislocated into the anterior chamber, causing the same atrocious pain which he had experienced before It was reduced by the same methods resorted to in the left Eserine quickly contracted the pupil The iris of the other eye was still paralyzed

On August 21, 1886, the lens of the first affected (left) eye had fallen below the centre of the pupil, and his myopia of 18 00 dioptries had changed to a hyperopia of 10 00 D Three months later the lens of the second (right) eye fell from its moorings, when he required + 10 00 D sph for distant and + 18 00 D sph for close vision

Case 3—C F H, æt 24, a brother of the above, desired me to examine him for glasses in December, 1885 He had a tremulousness of the lower middle portion of each iris, with a tilting backward of the corresponding part of the lens The optic discs looked very small and slightly elliptical Right V = $\frac{20}{XX}$, with — 8 00 D sph Left V = $\frac{20}{XX}$, with — 5 50 D sph ◯ — 2 25 D, cyl axis (unusual) 90° Inquiry as to the parentage and ancestry of these patients failed to show any intermarriage of blood relations A grandmother and an aunt were said to be very near as well as poor sighted

Case 4—E C, æt 31 years, was examined in February, 1884 Right eye staphylomatous, lens in lower part of ant chamber and calcareous T + 3 V = 0 Has suffered terrible paroxysms of pain in it for many months Left eye quite painful during the last few weeks, lens in ant chamber and adherent below to the posterior elastic lamina The upper part of the lens is tilted backwards, with the corresponding portion of the iris V = $\frac{20}{?}$, with — 6 00 sph He says that he has always been near sighted, and that a competent eye specialist told him years ago that his lenses were dislocated, that until a short time ago they would float about and come forward, but he could always replace them by a sudden movement of the head backwards I advised enucleation of the right eye, and did it under the influence of an anæsthetic While under the chloroform an effort was made to replace the left lens, but it was found to be too adherent to both iris and cornea for anything to be accomplished short of unjustifiable interference I therefore suffered him to return home, with orders to report again on the least change, expecting that sooner or later an iridectomy might be needed He was not seen again until one year afterwards, when I found the lens very much shrunken, opaque, and still adherent to the iris and cornea Doubtless the efforts at reduction had caused this change V = $\frac{20}{?}$, with + 10 00 D sph The eye free from pain

Cases 5 and 6 were simple, congenital displacements directly outwards, in young persons, with iridodonesis, myopia, and reduced acuity of vision

Cases 7 and 8—These, in addition to the above-named symptoms, had corectopia In both the pupils were exceedingly small, and were situated upward and outward One of them had nystagmus also

In none of these cases did the lens seem to be smaller than usual, and though I looked carefully for evidence of abnormal suspensory ligament, neither oblique illumination nor the ophthalmoscope enabled me to see any of its folds

Spontaneous Luxations of the Lens—These have been too numerous to record short of wearying you I will therefore simply mention a few points concerning them The largest number have occurred in cataractous patients who were past the meridian of life, though I have seen it by no means infrequently in youthful persons Some of these have been seen almost from the very point of departure, and on through all of the various changes to the end The following may be considered typical ones

Case 9—A C, æt 74, of full habit, right eye lost from corneal opacity following ulceration and treatment with ground glass when a youth Left lens slightly opaque I saw this patient from time to time for several years during the progress of ripening of the cataract, until he became very impatient, and anxious to have something done I then told him that if on his next visit to me, six months hence, it was not ready, I would hasten it by an iridectomy When he returned, a slight luxation with iridodonesis was to be seen I refused to operate until further changes were manifest He left me much disappointed and went to another, had his lens extracted and as I learned subsequently, lost much vitreous and became totally blind

Case 10—A feeble gentleman, æt 76, had senile cataract in both eyes The left lens was slightly

luxated downward, so that by artificial mydriasis he could see a little above the periphery of the lens I made a small iridectomy upwards, which was followed by a slight escape of vitreous, but it gave rise to no immediate trouble He recovered nicely, could see to read very small type with + 16 00 D spl , but, in about three months after the operation, the lens settled still lower, pressing upon the ciliary body, and he suffered most terribly until his death, which was supposed to be from softening of the brain His vision, however, remained remarkably good until the end

Case 11 —W W , æt 44, was seen in 1876 with matured cortical cataract in the left eye, which had been blind several years He never had injured it, there was no tremulousness of the iris, V = simple perception of light Right eye normal, V = $\frac{2}{x}\frac{2}{x}$ In 1882 a little opacity was to be seen in the right In 1884 a slight shaking of the iris could be noticed in the left The right gradually went on to blindness, but I refused to extract until he had abstained from liquor for three months (he was a steady drinker) An extraction was made with great ease, and he did well until the fifth day, when a hæmorrhage from the iris took place, followed by a very high degree of inflammation which closed the pupil An artificial one was made twice subsequently, and these also closed We finally succeeded in obtaining V = $\frac{3}{c}c$ He became anxious to have the left lens removed, but I made a downward iridectomy first, hoping that something might turn up before attempting to extract A small amount of vitreous escaped as the knife was withdrawn, but he did well for four days, when a hæmorrhage took place After all the blood had disappeared, a most beautiful keyhole-shaped pupil was to be seen, at the lower part of which a narrow, jet-black portion showed that a space existed between the lens periphery and lower corneal margin The lens trembled very much on the least motion of the globe This opening enabled him to walk about in moderately familiar places, in deed, all about our city, but not enough to satisfy his desires, so that I was constantly entreated to do something more I really feared to touch it, as it was practically the only eye he had, and in the light of my former experience with him, I expected its loss to follow an extraction He then visited many others of our profession, but fortunately they did nothing Over and over again did he visit me, and there hung the shaking lens, which almost tempted me to loosen its attachments, when, about nine months ago, he called upon me suffering the most excruciating pain in it, the cause of which I was at a loss to account for He was given a little cocaine and atropia, with orders to report again in a few days I saw nothing further of him for one month, when he presented himself with a beaming countenance and an almost clear lens, it having become liquefied Only a few minute specks were to be seen floating in its substance, and a few striæ hanging from its posterior border into the vitreous humor His vision = $\frac{2}{c}0$, with + 11 00 D sph , and has remained as good until the present date, when I see him every day riding or driving about our city

Case 12 —*Traumatic Luxation of the Lens* —Patrick D , æt 55, dislocated his lens into the anterior chamber by striking it with a "spaul" of stone while cutting rock in Ireland, thirty years before I saw him He says that his eye pained him terribly after the accident and he became blind He again struck his eye in the same way and manner and again suffered fearfully I found him, three weeks after the accident, with an iritis, an opaque lens in the anterior chamber, and tension + 2 His lens was removed and an iridectomy made, when, after four weeks, his vision became remarkably good, = $\frac{2}{c}0$, remaining so up to the present time, seven years after the operation

Case 13 is a striking contrast to the above H A , æt 59, was kicked by a horse a few years ago, which caused atrophy of the right eye The left is hard as a marble, the pupil widely dilated, the lens clear and floating about in the vitreous as in so much water The optic disc is atrophied and the central vessels curve abruptly over its edge Vision is totally obliterated And so one could go on with case after case showing the most opposite results from similar causes, were it not that you would accuse him of prolixity I will therefore briefly remark on the above report as follows

The three cases first mentioned corroborate the writings of others, as to the influence of heredity in congenital displacement of the lens

Cases 2 and 4 lead one to the conclusion that an eye with a congenitally displaced lens is an exceedingly weak organ, and very prone to progressive luxation, to cataract and to glaucoma

All of these cases were myopic, the myopia being due to lens anomalies and not to elongation of the eyeballs, as was proved both by the ophthalmoscope and by positive glasses, in the cases where the lens fell below the axis of vision

The permanent paralysis of the iris in case 2, after contact with the dislocated lens for so short a time, seems to be a point worth our consideration

I would also beg leave to call attention to the methods employed in replacing the lens in this case, and would suggest that, should one fail by all of these, he would be justified in evacuating the aqueous chamber by a free incision through the cornea, as every beginner knows that when he first attempted to extract a transparent, recently dislocated lens from the anterior chamber, no sooner was the incision made through the cornea than the lens bounded behind the iris, to his great mortification

The most fruitful cause of spontaneous luxation of the lens is, as far as my experience has permitted me to judge, subacute inflammation of the uveal tract Often have I seen it take place during the course of that many-named disease, "aquo capsulitis, keratitis punctata," etc I further believe that it is often the cause of the acquired myopia ("second sight") of elderly persons Not unfrequently, one meets with such patients whom he finds to be hyperopic, and who require strong positive lenses, even for infinite distance Again do they call, stating that their glasses serve them no longer, and we find that they can read better without than with convexes,

and see better with negatives at a distance than without, but when we look into their eyes we often find the iris and lens much closer to the cornea than before, and generally a congested condition of the fundus, with floating particles in the vitreous humor

Case 10 shows that the spontaneous cure of cataract is by no means impossible, that it cannot always be accounted for on the theory of a falling of the lens below the upper margin of the pupil, nor by that of traumatism and subsequent absorption, but that it does, in a small number of cases, first become loosened from its ciliary attachments, disintegrate, liquefy and regain transparency

In luxations of the lens from traumatic causes, such peculiar and marvelous results are so often met with that, were a book written on this subject alone, it would take rank with the writings of De Foe and other similar authors, and the writer of it would be considered about as truthful as was Herodotus prior to the excavations about Nineveh and Babylon

Resume

1 Heredity plays an important part in congenital displacement of the lens

2 Congenital displacement is a dangerous anomaly which is very prone to progressive luxation, to cataract and glaucoma

3 Most of the cases of congenital displacement are highly myopic, and the myopia is due to the malposition of the lens, and not to elongation of the antero posterior axis of the globe

4 Spontaneous luxation is in a very large proportion of cases due to congestion and subacute inflammation of the uveal tract, and the "second sight" or acquired myopia of elderly persons is often due to this cause

5 Partial spontaneous luxation of the lens occasionally results in the spontaneous cure of cataract, not, as is usually supposed, by the falling of the lens below the upper pupillary margin, but by degenerative metamorphosis and subsequent liquefaction

---

INJURIES OF THE FŒTUS DURING LABOR

Read before the Philadelphia County Medical Society, October 26, 1887

BY THEOPHILUS PARVIN, M D, LL D,

PROFESSOR OF OBSTETRICS AND DISEASES OF WOMEN IN THE JEFFERSON MEDICAL COLLEGE PHILADELPHIA

Though injuries of the child during labor are not frequent, probably they are much less rare than commonly believed In many instances they are recognized immediately after delivery, and they may spontaneously disappear, and in some their consequences are attributed to erroneous causes

Some of these lesions may happen in spontaneous labor, and others in artificial, whether the interference be manual or instrumental It is impossible to classify them according to their causes, and apparently the most satisfactory division is one resting upon the regions or parts affected Hence, in the paper now presented, injuries to the fœtus in labor will be divided into those involving the head and neck, those of the trunk, and finally, those of the extremities

Injuries of the Head and Neck —Contused wounds of the scalp and of the face, and incised, punctured, and lacerated wounds of the former are met with So far as contused wounds of the face are concerned, it usually happens that they follow difficult delivery with the forceps, especially if the instrument be a powerful compressor, so too these result if the blades are applied obliquely, or antero posteriorly to the head instead of to its sides But in most all cases the effects are trivial and soon disappear Punctured and incised wounds of the scalp have been made by the obstetrician mistaking a caput succedaneum for the fœtal sac Farmer mentions an instance of a wound thus inflicted leading to the death of the child from erysipelas a few days after birth More extraordinary is a lacerated wound of the scalp made in the effort to apply forceps, the operator introducing one of the blades between the scalp and the cranial bones An example of this terrible blunder is mentioned by Charpentier, and I have met with a similar case

Sloughing of a portion of the fœtal scalp has been observed following some cases of spontaneous labor Thus, Priestley[1] has reported a case of this kind, resulting in death eight days after delivery, the labor was protracted for forty eight hours because of a narrowed pelvic outlet Lizé[2] of Mans, states that in the case of a multipara, 30 years of age, the waters ruptured five days before the birth of her child which presented by the vertex, but occupied an occipito sacral position Five days after delivery, a slough involving almost the entire extent of the occipital bone appeared, three days subsequently it became detached and the child recovered

Bouchut[3] quotes from Lorain a case of gangrene of the scalp in a newborn child occurring in the service of Moreau at the Maternity The mother was a primipara, and the labor lasted forty eight hours, terminating spontaneously, the child died on the nineteenth day

Dr Goodell informs me of a case in which an oblique application of the forceps was made—one blade being in relation with the right frontal bone, and the other with the left occipital—and the right anterior portion of the head was so bruised that sloughing occurred a few days subsequent to birth, after the detachment of the slough a fatal hæmorrhage occurred

Depressions and fractures of the cranial bones, separation of their union to each other, fractures of the bones of the face, as well as disjunction of their articulations and joints, have been observed more or less frequently in cases of difficult labor, manual or instrumental—some of them, indeed, in spontaneous labor

In regard to depressions of the bones of the fœtal skull, some obstetricians have asserted that they are always accompanied by fractures That was the opinion of Danyau, of Lachapelle, and of Schroder

[1] London Obstetrical Society s Transactions vol i
[2] Annales de Gynécologie 1875
[3] Traité Pratique des Maladies des Nouveau Nes etc

But the following case,[4] given by Matthews Duncan, seems to strengthen the view held by most obstetricians, that such depressions may occur without the bone involved being broken The case was one in which persistent digital impression was produced on the right parietal bone of a fœtus during birth, by the finger of the accoucheur, who was endeavoring to cause rotation The result was slight, short, but frequently repeated epileptiform seizures, which lasted some time after the digital impression had disappeared, and were finally replaced by choreic movements Now it seems hardly probable that the pressure of the finger produced a fracture of the bone

Dugès[5] has given an instance of great depression in one of the parietal bones, not followed by any serious consequences The child was delivered by the feet through a pelvis of which the conjugate was estimated at three inches and a quarter Powerful traction upon the shoulders and upon the lower jaw was necessary to bring the head past the obstruction, and the parietal bone, which was in relation with the sacro vertebral angle, presented a depression half an inch in depth and two inches in breadth The infant was resuscitated with difficulty, then had convulsions, but in a few days was quite well, and in fifteen days the depression had entirely disappeared

Minor depressions or identations are sometimes seen, especially after the application of the forceps, and in rare instances such marks are permanent But we must not be in haste to conclude that these indentations found upon the head of a newborn child are proofs of instrumental delivery, for Osiander[6] has stated that, having delivered a child by podalic version through a narrowed pelvis, he found upon its head a depression into which the end of a forceps-blade accurately fitted, so that he himself would have concluded, had he ever a similar depression, that the delivery had not been spontaneous, but by the forceps

Fractures of the fœtal skull have been observed as the result of direct violence, as when a woman expels her child while she is standing, and it falls on the floor Or, again, a woman,[7] near the close of the second stage of labor, the child's head being at the vulvar opening, threw herself out of the window, and several fractures of her limbs, as well as a fracture of the child's head resulted

But apart from these cases in which the injury has resulted from direct violence, and those observed in delivery, whether spontaneous, manual, or instrumental, in narrowed pelvis, which will be referred to in a moment, fracture may occur when the labor is in all respects perfectly normal, so far as duration and facility are concerned Thus, Dr Charles West[8] has reported the case of an infant dying from convulsions nine days after birth, the labor having been an easy one and lasting but five hours, the mother had previously given birth to two living children, and these labors too had been normal Yet upon an autopsy of the third child, a fracture of the right parietal bone, with effusion of blood between the cranium and dura mater, the effusion being more than half an inch thick and occupying the entire fossa of the bone, was discovered He states in his report that fractures of the skull have been known to take place during easy labors, and wholly independent of any preternatural degree of ossification of the skull Monteith[9] mentions having attended a case of perfectly natural labor, yet the child had a fracture of the right parietal bone, there was a marked depression in the middle of the bone, and the fracture extended to the sagittal suture on one side, and to the coronal on the other

It is quite apparent that a case such as either of these might give rise to a medico-legal investigation, or to unjust censure of the obstetrician

Coming now to fractures of the bones of the cranium or face, or rupture of joints involving the maxillary symphysis, or the cervical vertebræ, or fracture of a verterbra, for it is claimed that usually the body of one is broken rather than a separation between two vertebræ, as the consequence of great traction occurring in manual or in instrumental delivery, an important question arises as to the amount of force that may be safely used either with hand or instrument In illustration of the great force which has been employed in forceps delivery without injury to mother or child, I quote the following from Dr Peugnet[10] He states

"I was called to Mrs K , a multipara, in labor with her third child The first two were delivered by craniotomy The vertex presenting, R O A , and impacted between the sacrum and the pubes, the conjugate diameter of the superior strait greatly contracted, I applied forceps, and had great difficulty in locking them Dreading the laceration which might ensue in this case from side to side lever action, I concluded to rely upon direct and steady traction My strength giving way, her husband held me round the waist, while the patient was held *in situ* on the dorsum by four women In forty five minutes I had the satisfaction of bringing the head down upon the perineum The delivery was then speedily accomplished Both mother and child, a girl, did well"

The least that can be said in regard to this case is, that the result was very remarkable, and it is doubtful whether the practice pursued could be repeated in any considerable series of similar cases without injury to both mother and child

Delore,[11] after remarking that the fœtal head may endure without injury, a great compressing force if applied to a large surface, and if made by a regularly concave surface, as that of the blades of the forceps, states that from his experiments he found a compressing force of one hundred kilogrammes did not cause a fracture But, on the other hand, if the blades slip, if the pressure is made upon a small surface, fracture follows the exercise of much less force Further, a blunt, angular body, such as the sacro vertebral angle, the spherical surface of which is described by a radius of two or three centimetres, produces a fracture with a force of twenty kilogrammes As the

[4] British Medical Journal, October 18 1873
[5] Quoted by Jacquemier Manual des Accouchements Paris 1846
[6] Given by Cieslewicz Verletzungen des Fœtus durch den Geburt shelfer Halle, 1870 Cieslewicz gives forty cases of fracture, fissure, contusion of nerves laceration of muscles, separation of epiphyses, etc occurring in labor he also reports two of rupture of the longitudinal sinus
[7] Quoted by Delore, Fractures du Fœtus, Dictionnaire Encyclopédique des Sciences Médicales
[8] Transactions of the London Medico Chirurgical Society, 1845
[9] London Lancet November 14, 1874
[10] Ohio Medical and Surgical Journal, 1878
[11] Op cit

force which is exerted in difficult labor is more than twenty kilogrammes, fracture results

Nevertheless, these results are not in complete accord with those of Goodell,[12] though, as will be seen, he is discussing the question of the amount of force of traction that may be safely used in a narrowed pelvis without injury to the neck of the child Nevertheless, the subject of injury to the bones of the head is also involved, and in only one instance, I believe, does he mention fracture of one of the cranial bones He states that he has on several occasions delivered living children after throwing on their necks a weight of 130 pounds He further says that, although exerting all the manual strength at his command, he has never seen the body part from the head, he mentions one instance in which there was not the slightest apparent injury to the neck though the sacral side of the head had been broken in Further, in another case, the force of traction upon the child's head, combined with suprapubic pressure, amounted to 200 pounds Stone[13] has more recently reported a case of podalic version and delivery by traction through a narrowed inlet, in which he put on the neck of the child all the force of which he was capable, using the pump handle movements described by Goodell The child was dead There was no fracture of the bones of the head,

"The spine had parted in the upper dorsal region during the traction upon the trunk, which was necessary to cause the shoulders to come low enough to reach the arms The cervical spine was not broken"

Delore's conclusion as to the amount of force followed, in pelvic narrowing, by fracture of the cranium of the fœtus is erroneous, or such injury ought to have been observed in all cases where a force even approaching 100 pounds were used

Champetier's[14] investigations as to the force that could be safely used in the delivery of the fœtus, led him to the following conclusions, the first of which does not correspond with the results obtained by Goodell, First, there is danger of fracturing one of the parietal bones, whatever the method of extraction, if the total force employed reaches thirty five to forty kilogrammes, the infant being at term, twenty to twenty two kilogrammes if it be premature Second, the inferior maxillary of a child at term will bear, without rupture, a traction of twenty five kilogrammes Third, the vertebral column of an infant at term was ruptured in three cases by a force of fifty kilogrammes

So far as objected that these results have been obtained by experiments upon dead children, and, therefore, they are not applicable to the force that may be exerted upon living ones, the answer of Matthews Duncan may be repeated He, after consulting physiological and physical authorities, could say that a child living and one recently dead were the same as to tensile strength

In this connection it is well to refer to the amount of traction which may be safely applied to the lower jaw of the fœtus, as stated by Duncan[15] from his own experiments It will be observed that his results are not the same as those announced by Champetier Duncan states

"It is now ascertained that a force of half a hundred weight (fifty six pounds) may, at least in some cases be employed by dragging the lower jaw of the fœtus without producing any calculated injury of parts."

He further says, that compound dislocation would be almost certainly fatal, and in one of his experiments this injury was done by a weight of fifty six pounds

Not only does Duncan's statement as to the force which the inferior maxillary bear without injury differ from that of Champetier, but the difference is still greater from that given by Delore, who makes this forty kilogrammes

Fractures of the cranium usually involve the parietal bones, but they may also occur in the frontal, in one of the temporals, or in the occipital Jacquemier first pointed out the separation between the squamous and the basilar portion of the occipital bone, to which some more recent writers[16] have directed attention without giving him just credit He has also stated that he has met with a fracture of the occipital in that part of the bone above the protuberance

Ruge,[17] referring to separation of the epiphyses between the squamous portion of the occipital bone and the articular part, states that Schroder is the only one who has recently drawn attention to it, and, notwithstanding its importance in regard to the life of the child, this lesion is not referred to in classic works as one of the immediate consequences of extraction The lesion may also occur in a narrowed pelvis, though the presentation be cranial In these cases there may be not only effusion of blood, but further compression by the squamous portion having its anterior inferior margin forced against the medulla.

On the other hand, severe injury of the frontal bone has been observed without serious consequences Thus, Dugès[18] saw a child recently delivered, and the left eye was almost completely outside the orbit, so great was the depression of the frontal bone, yet the infant did not have convulsions or any other grave symptoms

I have, however, seen protrusion of the eyeball in a newborn, following fracture of the frontal bone by Hodge's forceps, used in a case of tedious labor in a primipara, the delay being from an occipito sacral position, the child lived for a week after birth That an infant may survive very grave injuries in labor is proved by a case reported by Lamotte,[19] in which a surgeon, in a case of shoulder presentation, had torn away the arm, and then performed craniotomy, evacuating a large amount of the cranial contents, yet the child was born alive

[16] Thus Bednar Die krankheiten der Neugeborenen und Sauglinge, Wien 1863 refers to it as a hitherto unobserved injury
[17] Bulletin de thérapeutique, from Zeitschrift für Geburtshulfe und Frauenkrankheiten 1875
[18] Jacquemier op cit.
[19] Traité des Accouchements 1726

Zweifel[20] regards fissures and fractures of the cranial bones as only of clinical significance if a sinus be injured and consequent hæmorrhage occurs On the other hand, Delore[21] asserts that all these fractures are grave, on the ground that they may be accompanied by contusions of the brain Further, there may be hæmorrhages between the bone and the periosteum, in the cavity of the arachnoid, or between the pia mater and the brain If the solution of continuity be at the position of a sinus, there is frequently rupture of the vessel He adds that in all cases in which the head has undergone severe compression from dystocia, he believes hæmorrhages occur The significance of this last remark will be appreciated, especially when we consider the remote consequences upon the mental condition of the child, as urged more especially by some English observers

Injuries to the bones of the face are usually of the inferior maxillary This bone may be fractured, or separation of the mental symphysis may occur Ruge mentions cases in which, in addition to injury of the bone, there were lesions of the soft parts—as, for example, tearing of the skin at the angle of the mouth, as well as the mucous membrane of the pharynx and rupture of the genioglossus

Yet if we fail to use traction upon the lower jaw in cases of difficult head last labors, we miss what may prove an important means of delivery in some cases, and which may be of great value when other means fail Some years ago, in a case of narrowing of the pelvic inlet, having failed to deliver with forceps, I performed podalic version, and sought to deliver by traction, while a consultant aided with supra-pubic pressure I am confident I did not use the force which some operators have safely employed under similar circumstances, yet the cervical vertebræ gave way, either by separation or by fracture, and I found apparently nothing but the integument holding the head to the body I then succeeded by traction upon the inferior maxilla, supra-pubic pressure assisting, in bringing the head into the pelvic cavity

That the head may be left in the uterus, the body being dragged away, is a fact proved by occasional instances in the history of obstetrics In other cases the division has been made, not by rupture, but by cutting through the neck An instance is reported[22] in which the obstetrician, failing to deliver the head in a case of shoulder presentation, after detaching the arm and bringing down the feet, performed decollation, and the head and the placenta remained in the uterus for forty days Freund mentions a case in which the head was left in the uterus for ten years

Probably the most remarkable case of multiple injuries to the face has been recorded by Petit[23] The face presented, rupture of the uterus occurred, and the woman died undelivered, though the forceps had been used The autopsy of the child showed multiple separations of the bones of the face, and fractures

Paralysis of one of the facial nerves has been observed most frequently, but not exclusively, after the use of the forceps In a paper read before the American Gynæcological Society in 1885, I have referred to eight cases of spontaneous facial hemiplegia, and also mention one case observed by Seeligmuller, in which the paralysis affected both sides of the face But the disorder usually occurs from the use of the forceps, and is caused by the pressure of one of the blades at the stylo-mastoid foramen, or a little in front of the lobe of the ear Landouzy, who has best described the affection, has remarked that in the infant the complete absence of the mastoid apophysis, and the slight development of the auditory canal, favor the possibility of this compression of the facial nerve near its point of emergence In six weeks, according to Parrot and Troisier, recovery usually takes place in paralysis of the facial caused by forceps Many cases however, are well in ten days Nevertheless, while recovery is the rule, it should be remembered that in some the injury is permanent Duchenne[24] refers to two patients, one 15 years old, and the other 5½ years, in each of whom the paralysis continued

It should also be observed that there may be facial paralysis in the newborn caused by protracted labor and intracranial hæmorrhage Injuries of the sterno cleido mastoid muscle have been observed by several In reference to torticollis of obstetric origin, Stromeyer and Dieffenbach explained the affection as resulting from improper application of the forceps, the muscle being bruised or torn Nevertheless, this explanation is rejected by Saint-Germain as not plausible A very large proportion of infants that have wry-neck, are born with pelvic presentation, and it is asserted that in the traction exerted rupture of a greater or less number of the fibres of the muscles take place, and a hæmatoma follows, finally, the contractions of the cicatricial tissue result in drawing the head into its unnatural position One of the first references to tumors of the sterno cleido mastoid was made by Melchiori[25] in 1862 He spoke of them as indurations of muscle, sometimes met with in young infants, and to which he found no reference in authors He met with the disorder four times, and he described the affection as an indurated, plastic deposit, while he mentions temporary deformity of the neck, he does not mention any case in which this was permanent In referring to the etiology, he suggests that compression of the muscle or laceration of some of its fibres may take place during labor

The next year both Dr Wilks and Sir James Paget[26] met with cases of what they described as chronic induration of the sterno cleido mastoid An other case of the affection was reported the same year by Harris, and thus the published cases in a few months were at least six, but no reference was made by any of the reporters to the previous observations of Melchiori

Bryant,[27] in 1863, reported two cases of thickening of the sterno cleido mastoid One patient was 4

[27] London Medical Times

the other 8 weeks old when he saw them, in each instance the birth was with pelvic presentation

Probably in all the cases, or at least in a majority of them, the disease was hæmatoma. Nevertheless, Blachez[28] regards these tumors as caused by an interstitial myositis in consequence of traction upon the muscle He describes the tumor, observed in one of his patients, as elastic, almost painless, and the size of a pigeon's-egg, it was situated in the right sterno cleido mastoid, and was not discovered until two or three weeks after birth, when the attention of the parents was called to it by the infant's keeping the head inclined to the right side

Zweifel recognizes injuries of the sterno mastoid muscle in labor as a cause of torticollis

Professor Albert,[29] of Vienna, referring to a child with torticollis, stated that the sterno cleido mastoid may become contracted during intra uterine life, or be injured during birth In breech presentations, and in difficult forceps delivery, a laceration of this muscle may occur, and be followed by inflammation and contraction

While such injuries are more frequent after head-last labors, yet they are also met with in vertex presentations, and when the forceps has been applied

On October 2, 1861, a paper was presented to the London Obstetrical Society by Dr Tyler Smith for Dr W J Little, the title being "Upon the Influence of Abnormal Parturition, Difficult Labors, Premature Birth, Asphyxia Neonatorum, on the Mental and Physical Condition of the Child, especially in relation to Deformities "[30] In this paper, which by the way mentions two cases of wry neck, that he attributed to difficult labors, the author says

"It is impossible not to connect the persistent affections of the intellect, of volition, and of organic life, with the injury the several nervous centres suffered in some instances before the fœtus had reached the maternal pelvis, in others whilst in transit through it, and in a third set of cases, where the fœtus was exposed to neither of these kinds of injury, it suffered from asphyxia neonatorum, suspended animation, and its concomitant congestions, effusions, capillary apoplexies of the brain, medulla oblongata, and spinal cord "

Dr Langdon Down, in discussing the obstetrical aspects of idiocy, stated that in a very large number of cases of idiocy the subjects were born after difficult labors, these being unusually tedious, and he held that if a neurotic tendency was present the tedious labor and suspended animation might determine the catastrophe, where otherwise all might have gone fairly well

The following note from one of Dr Little's[31] correspondents may be of some interest, it is in reference to a young man in regard to whom inquiry had been made by Dr Little

"I have again ascertained he was asphyxiated for two hours when born, and that he has always been a weak creature, very slow in mental development with difficulty in speaking trembling and shaky, unable to fix his attention on a book, and a bit of a punster" The final statement "a bit of a punster," is conclusive as to the intellectual feebleness of this unfortunate man

These views are further strengthened by the statement of Dr Arthur Mitchell[32] that he believes there is a connection between difficult labor and idiocy

Injuries of the Trunk—The chief lesions of the trunk are rupture of the connections between the dorsal vertebræ, or fracture of one of these, injuries to the abdominal wall by a badly directed blunt hook, effusion of blood in muscles, similar to those that have been referred to as occurring in the sterno cleido-mastoid, retropleural hæmorrhages along the spinal column in case rupture of this column occurs, hæmorrhage into the abdominal or thoracic cavity, and collections of blood beneath the capsule of the liver, or of the kidneys, and rupture of the sacro iliac joint Ruge has collected forty four cases of injuries to the fœtus occurring in extraction after version, and twenty nine of injuries in pelvic presentations, in the former there are three of rupture of the sacro iliac joint It is probable, as suggested by Zweifel, that some cases of ankylosis affecting this joint, of which the etiology is obscure, are to be attributed to injury in birth

Zillner[33] has reported a rupture of the sigmoid flexure occurring in labor

Injuries of the Arms—In connection with these lesions those of the scapula and clavicle, which belong to the arms rather than to the trunk, will be considered Delore states that fractures of the humerus are more frequent than all others, since they are usually readily cured, and are generally caused by *maladresse*, they are rarely published But he further says that this accident may occur in the hands of the most expert accoucheur if the pelvis be contracted They most frequently occur in the disengagement of the arms after podalic version when extraction is necessary, and they may also happen in pelvic presentation, but usually, if we do not have to extract the child—that is, if the expulsion can be left solely to nature—the arms will not ascend, but remain applied to the chest Smellie[34] states that he fractured the humerus in a case in which he turned and delivered by the feet, and this is the only one he gives, while he mentions three cases of fracture of the femur, two occurring in the practice of his assistants, and one in his own

All obstetricians agree that in bringing down an ascended arm it is important no pressure be made until the internal angle of the elbow is reached, and that three or four fingers should be employed, and not one or two Pajot regards it as important that the posterior arm should be liberated first Kustner[35] describes separation of the epiphysis of the head of the humerus from the diaphysis as one of the injuries

[33] Centralblatt für Gynakol 1885
[34] Sydenham Society's edition of Smellie's Midwifery, vol iii pp 296 297 This great obstetrician in the first volume op cit remarks In laborious or preternatural cases when considerable force hath been used in delivering the child the whole body ought to be examined and if there is any mark or contusion on the head it will disappear if anointed with pomatum and gently rubbed off or chafed with the accoucheur's hand if any limb is dislocated or broken it ought to be reduced immediately luxations though they seldom happen, are more incident to the shoulder than to any other part the humerus being easily dislocated and as easily reduced The bones of the arm and thigh are more subject to fracture than any other of the extremities the first is easily cured because the arm can be kept from being moved but a fracture of the thigh bone is a much more troubles me case because over and above the difficulty of keeping the bones in a proper situation, the part is often necessarily moved in cleaning the child "
[35] Ueber die Verletzungen der Extremitäten des Kindes

of labor which may be overlooked, or falsely regarded as a luxation, fracture of the neck of the scapula, or injury to nerves Fractures of the clavicle, separation from its sternal attachment, transverse fracture of the scapula, separation of the epiphysis of the neck of the scapula, injury of the acromion process, and dislocation of the humerus, have been observed

Fracture of the clavicle is most frequently caused by pressing directly with one or two fingers in the endeavor to bring the head through the pelvic inlet after podalic version, or in pelvic presentation McClintock, in one of his annotations to the Sydenham Society's edition of "Smellie," observes "Although Smellie gives no example of fracture of the child's clavicle during delivery by the pelvic extremities, yet, in my experience, it is a bone very apt to be broken by the manipulations of the accoucheur, more so even than the humerus, this may, perhaps, be explained by its greater degree of ossification"

Paralysis of the Arm—Sinkler recognizes hemiplegia as, in some cases, the consequence of injury at the time of birth, either from the forceps or from the pressure of a prolonged labor Nadaud gives seven cases of paralysis of the arm attributed to the forceps, the first one of this injury reported is one of Smellie's Jacquemier mentions an instance of paralysis of the deltoid following a long and difficult, but spontaneous, labor, the recovery was complete in fifteen or twenty days He attributed the disorder to compression of the axillary nerve against the humerus at the point of its attachment to the deep face of the deltoid Fasbender found a tumor, as large as a pigeon's-egg, situated above the right clavicle, in an infant soon after delivery, the hæmatoma gradually disappeared, but at first there was paralysis caused by nerve compression Delore suggests that paralysis may be caused by the rupture of a nerve trunk near its connection with the spinal cord He states that this accident is not rare in the newborn or in young infants as a consequence of traumatism, it is followed by incurable paralysis, which is compatible with life if an upper member only is affected

Disengagement of the extended arms in pelvic deliveries, traction upon the axilla in delayed delivery of the body in vertex presentation, the traction in some cases being with the blunt hook, in others with the finger, have resulted in paralysis of the arm So, too, the same disability has followed a case in which the arm has protruded in shoulder presentation, and delivery effected by podalic version

Luxation of the humerus has, in some instances, been mistaken for obstetric paralysis Further, it is important to distinguish between cerebral and traumatic paralysis Duchenne[36] gives an instance in which there were both cerebral and obstetric paralysis, the latter consequent upon a fracture of the ulna near the elbow

Fractures of the femur may be spontaneous, or consequent upon artificial delivery Meyer[37] has recently reported two cases in which spontaneous fracture of the femur was observed, in one a single femur was broken, but in the other both femurs In May, 1847, Dr Vanderveer[38] reported a case of such fracture in childbirth

But probably more fractures of the femur are to be attributed to the attempt to pull down a lower limb in pelvic presentation when the presenting part is already partially in the mother's pelvis, before pressing up that presenting part, or from the use of the blunt hook Delore's experiments show that with the untired finger traction to the amount of fifteen kilogrammes may be made upon the groin, and this cannot break the femur If a force of fifty-five kilogrammes is employed upon the femur, fracture occurs, if the instrument be perpendicular to the bone, the latter gives way with a pressure of twenty kilogrammes

Again, the bone has been broken, or that which is equivalent, separation of the epiphyses been caused from traction upon the leg A R Simpson mentions an instance in which, podalic version having been performed, the right lower limb brought down, and traction made, subsequent examination showed that there were three such fractures [39]

Luxations of the femur consequent upon obstetric operations, according to Ruge, are exceedingly rare, upon 300 autopsies of newborn infants he did not find a single true dislocation of this bone

Kustner, in referring to luxations of the hip, speaks as follows

> "Goschen relates a case in which Langenbeck reduced such luxation after the subject, a girl, was 13 years old, and mentions in this connection that Stromeyer had met with 20 cases. The only possible way in which this injury could occur would be by sudden and violent force drawing down the limb, and then dislocation upon the ilium might result But the force must be great I have suspended to the leg of a child, from six to ten minutes, a weight of from thirty to forty kilogrammes, without any injury to the joint"

Complete paraplegia in connection with facial paralysis of the right side has been observed following a difficult labor in which the forceps was used Examples of rupture of the spinal cord, in connection with rupture of a vertebra, have been observed, and, of course, paralysis of the lower limbs *It is* remarkable that in two such cases the children lived for some hours Paraplegia in the newborn is, as Nadaud states, usually an evidence of serious lesion of the cerebro spinal organs, and the child dies after a short time

I think the study of these cases of obstetric injuries, which might be greatly extended—for much more remains unsaid than has been said—ought, in the first place, to lead us to a larger charity for fellow practitioners, as many of the most serious injuries in childbirth may occur without the slightest blame necessarily attaching to the accoucheur

Another lesson is that an important distinction should be made, as urged by Ruge, between podalic version and extraction, never resorting to the latter, unless absolutely necessary, after the performance of the former, and thereby many of the obstetric lesions of the fœtus may be avoided Very wisely, Lamotte says, referring to the injuries that may be

[36] See Nadaud, op cit

[38] New York Medical Journal
[39] Edinburgh Medical Journal, 1880

done in labor to the child by the accoucheur, "The hand improperly used is more dangerous than any instrument"

Again, the question arises as to the safest manual means for the delivery of the head in head last labors In Cléslewicz's collection of cases of injuries of the fœtus in labor, there are several in which very serious consequences resulted from employing the Prague method One of these, reported by Gusserow, showed, upon post mortem examination, rupture of the vertebræ and most of the soft parts of the neck so complete that the head was attached to the trunk only by the skin and the vertebral arteries Ruge, rejecting both the Prague and the Vienna method, prefers elevation of the occiput, bringing the face down, and carefully conducted expression, as least liable to injure the fœtus

Another question of practical interest, is the best method of delivery in pelvic presentations, when interference is necessary Should we follow that employed by Goodell, in all cases bringing down a foot as soon as possible, and thus be commander of the situation, in case necessity for extraction arises? Must we use the blunt hook? Is the application of the forceps to the breech to be generally advised?

Again, while treatment of fractures of an upper limb, or of the clavicle, is said to present usually no great difficulty, can a similar statement be made as to fracture of the femur? What method of treatment is best?

In depressed fractures of the skull, is it not probable that some lives might be saved by the use of the trephine? and in other cases, not followed by death, perfect mental integrity insured?

Finally, many questions as to the diagnosis of obstetric paralysis of the newborn arise, and, also, as to when and what treatment should be employed

DIPHTHERIA

Read in the Section on Diseases of Children, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY H LANDIS GETZ, M D,
OF MARSHALLTOWN IOWA

I am well aware that the subject I have selected is one which has been again and again discussed, sometimes by men who have evidently had experience with the disease, while at other times it is evident that the individual who has undertaken to discuss the disease had in reality only had experience with ulcerated tonsilitis, or what may be called "homeopathic diphtheria" It is not my purpose to take up your valuable time in the discussion in detail of the definitions, synonyms and history of the disease, but to consider such general conditions pertaining to symptoms, causes and treatment as I have formed opinions concerning, and which I believe are not fully set forth in all particulars, in even the various treatises upon the subject

Let us admit the disease to be one of the zymotic class, specific, highly infectious, slightly contagious, the chief early symptoms of which are malaise of a few hours duration, with or without chills, followed by slight fever, which is indicated by slight increase of pulse and increased marking of temperature by the thermometer There is seldom vomiting, and very seldom do we find convulsions at this stage of the disease

The local symptoms, are at this stage of the disease, of so slight a character, so far as pain and inconvenience in deglutition are concerned, that unless the local lesion of false membrane formation is suspected, it would be readily overlooked, especially by the inexperienced The early symptoms of diphtheria, are so mild in form in the majority of cases, that the real nature of the disease is readily overlooked, by physician, parent and patient Any physician, who has had extensive experience with the disease, I believe, will bear me out in the statement, that time and time again, is found an extensive and well developed exudation upon the fauces and perhaps extending up over the arches of the palate and over the uvula, where the local inconvenience was so slight, that the parent did not even surmise the real nature of the trouble, sending for the physician simply because the child had not been feeling well, for twenty four or thirty six hours, and desired a physician to determine what the difficulty was To be called twenty four or more hours after membrane formation has set in, which I believe is always if sought for, found to exist quite as early as any *noticeable* degree of fever exists, is *late* to assume charge of a genuine type of diphtheria when attacking an individual whose system is in condition to furnish fertile soil

The severity of the disease, as I shall endeavor to show in this paper, is not and cannot be usually discovered by the constitutional disturbances found to exist in the symptoms during the first thirty six hours, in fact, the severity of the attack is seldom to be judged of by the constitutional symptoms so far as relates to febrile disturbances, being, in the majority of cases, only moderate in degree, frequently very slight, and only occasionally is very high temperature found with corresponding pulse The severity of the attack being influenced by the soil in which it develops, and that *alone* determining it, and this in time proportionate with the fertility of the soil, as the varying systems would furnish for its development

As an illustration let us admit that the disease may possibly develop with equal readiness in all tissues, all things equal, in all persons The system, however, in some persons is in such a state, blood and other elements, as to afford but barren soil, while in others it is fertile, in the former the individual is proof against constitutional contamination, while in the latter the system becomes rapidly saturated, unless something is done, either to destroy the disease germs or to render the system proof against their inroads

Two classes of remedies then are indicated germicides and fortifiers Germicides may be applied locally and termed direct, and constitutionally and termed indirect, the latter so altering the character of the blood that the germs, as soon as reaching it, perish

Fortifiers constitute 1 Such remedies as would, in the first place, by local application, protect or place in such condition, tissues of the fauces and others, as to prevent the lodgement and development of the disease 2 The second class of *germicides* here apply 3 The class of remedies, hygienic surroundings, food and elements which tend to improve and strengthen the quality of the blood and to bring the system into such a condition as will most nearly render barren the soil for the development of the disease

Diphtheria is a disease which runs when terminating fatally, usually a rapid course, the majority of cases terminating in four to six days Hence, whatever is done with a view to averting fatal results and controlling the disease, must be done promptly and thoroughly, it matters not whether the disease be first constitutional, or first local, or both In this connection I quote the following extract from a paper contributed by myself over five years ago "Concerning the seat of the disease there can be little doubt, nay, there can be *no doubt* in the minds of those who have had experience with it, that if it is not a constitutional disease at the outset, it very soon becomes such And if the disease is communicable through drinking milk, etc, while micrococci may attach to the fauces and tonsils and thence originate the disease, it is quite as likely that some may be, and are carried into the stomach, and so on into the circulation And in such an event it would be possible for the disease to be sometimes first constitutional and at others first local In either event, if the disease germs are lodged any where in the system, local or otherwise, the constitutional and the local symptoms will soon be manifest, so that the treatment resolves itself into local and constitutional from the outset At any rate this is the only safe mode to adopt In some instances, if the disease were purely local (which I believe it may sometimes be), and we had some means by which we might to a certainty settle this point, we might then adopt a purely local treatment, perhaps with success, if the cases were recognized in their *incipiency*, but having no such means we must be alike prompt in local and constitutional treatment, if we would save our patient, for delay in either is almost certain death" (Concerning the seat of the disease, there can be little doubt)

As to what constitutes promptness and thoroughness is explained in the further quotation from the same paper

"If you begin treatment within twelve hours from the commencement of membrane formation, there should be no fatal results If you begin treatment eighteen to twenty hours after the commencement of membrane formation, you may expect to lose a patient occasionally If you begin treatment twenty four hours after the commencement of membrane formation, you may, in spite of all you can do, expect a great many fatal results"

Now I imagine I hear many saying "it is not diphtheria he is discussing," but it is I imagine I hear others saying "if the disease is of malignant type, it matters little *what* or *when* you do for the patient, few, if any, cases will recover" Here arises the query, are not all germs which produce the disease alike, admitting there may be occasionally an imperfect one? And is it not more particularly the soil in which the germs lodge, than that it is, there is a simple and a malignant type of the germs, malignity depending upon, or being due to *quantity* and *not quality* of germs? In the prevention of development of quantity, is the secret of success, in treatment, in the majority of cases of diphtheria, especially the class of cases that would and do suffer from blood contamination, not due to immediate or partial, laryngeal stenosis, resulting in immediate or gradual asphyxia, due to retention of carbonic acid in the blood, but due to overwhelming quantities of the disease germs If there is any virtue in treatment of the disease by medicine or otherwise, the importance, therefore, of early care is readily understood

Having seen that the disease under consideration is one which is likely, owing to its mild symptoms to mislead even the careful observer, it becomes then the duty of the physician to not only examine carefully the throat of every adult whom he may be called to see, when the same has been exposed to diphtheria, even if no local inconvenience is complained of, but also to examine carefully the throat of any child who complains (whether diphtheria is known to exist in the locality or not) of slight inconvenience in swallowing or an uncomfortable feeling in the throat It is further, the duty of the physician, to advise persons who have children, to examine carefully the throats of those who may complain or seem ill in the least, when diphtheria *exists* in the locality, and also to send for a competent physician if anything resembling membrane is discovered If they have any concern for the safety of the child, they had better send a hundred times uselessly, than to delay once, a dozen hours too long
